tumor-defining rings, beam aperture, and crosshairs that should be observed in the alignment film when the patient is correctly aligned. The treatment planning program creates a spherical model of a globe that is scaled to the ultrasonically determined length of the patient's eye and the position of the tantalum rings previously sutured to the sclera, determined by orthogonal radiographs taken of the patient in the treatment position (gazing in three different directions). The structures of the eye are added to the model, including the anterior chamber depth and thickness of the lens obtained ultrasonographically. The program then superimposes on this globe a three-dimensional model of the tumor based on fundus pictures and ultrasonograms. The fundus photographs are especially useful for very posterior tumors and tumors abutting the optic nerve where it is impossible to surround the tumor with marker rings. Two tumors can be created if needed, e.g., if there is a tumor with an irregular shape. Tumors in the iris or ciliary body, for which placement of marker rings is unnecessary, are drawn from clinical and ultrasound information.

The computer program permits the user to view the eye in any direction it rotates, while the eye follows a user-controlled fixation point. This procedure improves the ability to choose the orientation of the eye relative to the beam that best covers the tumor while simultaneously excluding sensitive normal structures, i.e., the lens, cornea, macula, and optic nerve.

The program automatically designs an aperture that gives a 3 mm margin around the tumor, at which the dose falls to 50%. This margin may be reduced to 2.5 mm for a tumor border at the limbus or increased to 4 mm for a patient without surgical markers. The program calculates the maximum and minimum depths of the tumor and allows the user to choose proximal and distal margins to give the needed beam range and modulation. The program calculates dose distributions on the fundus displayed in the geometry of a wide-angle fundus photograph (Fig. 150.3) and in any plane through the eye (Fig. 150.4). It also calculates dose-volume histograms for the tumor and many structures of the eye.

**FIG. 150.3** Wide-angle fundus photographs and isodose curves superimposed on an eye model from the treatment planning program. The four tantalum rings are shown in magenta and numbered 1–4. The tumor is outlined in green, and the 90% dose curve is shown in dark blue.

**FIG. 150.4** Isodose curves in a vertical plane through the eye parallel to the beam direction for the case shown in Fig. 150.3. The tumor is shown in red, and the yellow cone represents the optic nerve. The innermost magenta line corresponds to the area

receiving 100% of the dose (70 CGE), and the outermost yellow line corresponds to the area receiving 10% of the dose (7 CGE).

## Treatment Techniques

A high degree of accuracy in positioning the patient is achieved with the use of a headholder attached to the proton beam collimator. The headholder allows controlled rotation of the head around two mutually perpendicular axes intersecting at a point that is positioned accurately on the axis of the collimator.

The patient is seated in a specially designed chair, and his or her head is immobilized with a bite-block made of a dental impression compound and fastened to the headholder. Individually contoured plastic masks mounted into a frame are also used for head fixation (Fig. 150.5). Orientation of the patient's eye is established by voluntary fixation of the eye to be treated (the other eye is covered) on a small light that is attached to the collimator. If the vision is poor in the eye to be treated, the other eye can be used for fixation. The eyelids are held open with a lid speculum.

**FIG. 150.5** Patient seated in headholder with plastic mask and bite block. The light represents the radiation field at the entry point on the ocular surface. The lids are retracted out of the field prior to the start of

treatment.

The eye is monitored using a high-magnification closed-circuit television system with its effective viewing point on the beam axis. This system provides a magnified image of 10 times the size of the patient's eye and permits continuous monitoring of the eye's position throughout the procedure. The alignment of the proton beam is achieved with orthogonal X-rays. The lesion, defined spatially by the radiopaque tantalum rings, can be positioned by translating the headholder until it is in the desired position relative to the beam axis. For tumors treated without surgical localization, a light beam coaxial with the central axis of the proton beam is used to position the tumor relative to the beam during treatment.<sup>8,20,21</sup> Positioning is achieved with a fluoroscopic system that provides a virtually instantaneous picture held on an image-storage device. This system hastens alignment and assists in confirming eye immobilization during treatment. The alignment procedure lasts approximately 15 minutes. The patient is asked to fixate, and the eye's position is observed on the television monitor in the control area. The treatment field is checked with a beam-simulation field light, and if the position and fixation are satisfactory, the treatment begins. If eye movement of more than 0.5 mm is observed, the treatment is halted immediately. Each treatment takes approximately 1–2 minutes, most without interruption.

## Radiation Dose

The standard dose administered for most tumors is 70 Gy (RBE) delivered in five equal fractions in 5 days (63.6 proton Gy times 1.1 relative biologic effectiveness equals 70 Gy (RBE)). Dose fractionation increases the radiosensitivity of tumor tissue, as increased oxygenation of hypoxic tumor cells occurs between fractions. We selected large fractions based on favorable clinical results demonstrated with the use of a small number of relatively large dose fractions<sup>10,22</sup> in patients with cutaneous melanomas. At the prescribed dose of 70 Gy (RBE), we estimate that the optic nerve and macula receive the full dose when the tumor is less than 1 mm from these visual structures, half the dose (35 Gy (RBE)) when the tumor is located 3 mm from these structures, and a small dose ( $\leq 15$

Gy (RBE)) when the tumor is peripheral (beyond 9 mm). As part of a randomized clinical trial to establish safety and efficacy of a dose reduction, 94 patients received a lower dose of 50 Gy (RBE).<sup>23</sup> No significant differences were found between patients who received the standard dose and those who received the lower dose with regard to tumor control and ocular complications. Thus, the optimal dose level to achieve tumor control and minimize ocular morbidity has not been established. Nevertheless, in select patients, i.e., those with small- or medium-sized tumors located near the optic nerve or fovea, a dose of 50 Gy (RBE) is chosen in an effort to reduce vision-threatening treatment complications. At several facilities in Europe, a total dose of 60 CGE (cobalt gray equivalents) is given in four equal fractions over 4 days.<sup>24-26</sup>

## Follow-Up

Follow-up examinations are performed 6 weeks after treatment and then every 6 months during the first 5 years and annually thereafter. Fundus photography and ultrasonography are performed at varying intervals for documentation of tumor regression. Annual liver function tests are recommended and may be followed with abdominal scans if indicated. Lifetime follow-up is completed for all treated patients who enroll in a uveal melanoma registry, and data obtained through these follow-up efforts have been utilized to evaluate the efficacy and safety of proton therapy in terms of visual and survival endpoints.

## Clinical Findings in Treated Patients

To date, more than 4000 patients with uveal melanomas have been treated at Massachusetts Eye and Ear Infirmary and Massachusetts General Hospital. Bilateral involvement and extrascleral extension are rare (less than 1% and 4%, respectively) as is treatment of iris-only melanomas (less than 1% of patients). The mean age of patients with choroidal or ciliary body tumors at the time of diagnosis was 61 years. Diagnosis before age 40 is uncommon, representing 11% of treated patients. The median basal diameter of treated patients was 13.0 mm (range: 5.0–28.0 mm) and median tumor height was 4.0 mm (range: 0.6–20.1 mm). Using the TNM

classification of tumor size (American Joint Committee on Cancer, 7th edition, 2010), almost equal numbers of patients were classified as T1 tumors or T2 tumors (approximately one-third in each group). Fewer patients were diagnosed with T3 and T4 tumors (23% and 14% respectively). More than two-thirds of treated tumors were located within 3 mm of the optic nerve or macula. Approximately 25% of the patients had 20/20 or better visual acuity at presentation, and fewer than 10% had visual acuity of counting fingers or worse.

## Results

### Tumor Regression

The majority of treated tumors show some regression after the first 6 months of treatment, with a usual range between 1 and 24 months.<sup>27</sup> Disappearance of the lesion, or formation of a flat scar, is observed in 15% of eyes. Resolution of a secondary serous retinal detachment is usually the earliest finding. Detachments can transiently increase in size during the first few months after treatment, but most eventually resolve. Continuous regression of the tumor over several years is frequently observed. Tumor regression is thought to be due primarily to direct killing of tumor cells by irradiation and secondarily to the effect of radiotherapy on the tumor vasculature. Cell death from irradiation is achieved by damage to chromosomal DNA, with subsequent loss of proliferative potential. Damage to DNA is lethal when the cell enters mitosis. Delayed regression, observed in some irradiated tumors, is probably due to prolonged intermitotic phases of melanoma cells. This protracted pattern of tumor regression has been supported by histologic studies of tumors enucleated at varying times after proton therapy, which showed a greater decline of mitotic figures with longer periods between irradiation and enucleation. Tumors enucleated more than 30 months after irradiation had no mitotic figures.<sup>28</sup> Rapid regression of tumors has been associated with higher rates of metastasis in both proton-irradiated<sup>29</sup> and plaque-treated patients,<sup>30</sup> suggesting that more aggressive tumors, due to more rapidly dividing cells, are more radiosensitive.

The presence of some mitotic figures in irradiated melanomas examined after enucleation for radiation complications does not indicate that irradiation has failed to sterilize the tumor. The presence of morphologically intact cells is not evidence that these cells are viable, since they may be programmed to destruct in the next mitotic cycle. These cells most likely are incapable of cell division, and the only proof of cell viability after irradiation is local recurrence of the treated tumor.

## Visual Outcomes

Visual acuity after proton beam irradiation depends on the size of the tumor and its location relative to the fovea and the optic nerve<sup>31</sup> (Fig. 150.6). In eyes with tumors located farther than 3 mm from these structures, tumor destruction usually occurs without functionally significant radiation vasculopathy.<sup>32</sup> In a study of 558 patients who had undergone proton therapy for small- to moderate-sized tumors located within 4 disc diameters (DD) of the optic nerve or macula, the 5-year rate of vision loss to worse than 20/200 was 68%. Risk factors for vision loss included dose to the macula, tumor height, poorer baseline vision, and a history of diabetes.<sup>33</sup> In a multivariate regression model,<sup>34</sup> distance of the tumor from the optic nerve and macula, tumor height, baseline visual acuity, degree of retinal detachment, history of diabetes, and tumor diameter were found to be associated with vision loss. Coefficients derived from this model were used to calculate risk scores, which were then used to estimate probabilities of vision loss. The probability of developing significant vision loss (worse than 20/200) by 10 years after proton therapy varied between 16% for patients in the “low-risk” category (Fig. 150.7) to 99% for patients in the “high-risk” group.

**FIG. 150.6** Kaplan–Meier estimates of vision retention (at least 20/200) in patients with a baseline visual acuity of 20/100 or better, by height ( $\leq 5$  mm versus  $> 5$  mm) and distance to the optic disc and macula ( $\leq 2$  disc diameters versus  $> 2$  disc diameters). (Modified from Gragoudas ES, Lane AM, Collier JM. Charged particle irradiation of uveal melanoma. In: Albert DM, Miller JW, editors. Albert and Jakobiec's principles and practice of ophthalmology. 3rd edition. Philadelphia: Elsevier; 2008. p. 4892. Reproduced by permission of Elsevier.)

**FIG. 150.7** (A) Patient with macular tumor, 1.4 mm in height, located  $\frac{1}{2}$  disc diameter from the fovea. Visual acuity prior to proton irradiation was 20/20. (B) Tumor has regressed to 1.2 mm and visual acuity remains 20/25 at 39 months after irradiation.

At greatest risk of vision loss are those patients who have tumors located near a structure that is critical for visual function. Large tumors are associated with several factors that can impair visual function such as exudative retinal detachments (approximately three-quarters of patients who presented at Massachusetts Eye and Ear Infirmary (MEEI) with large tumors had retinal detachments) and inflammation from tumor necrosis. Additionally, many large tumors are in close proximity to the optic nerve and/or macula (Fig. 150.8). For example, in our series of proton-irradiated large tumors (height  $\geq 10$  mm (or  $\geq 8$  mm if optic nerve involved) or height  $\geq 2$  mm and diameter  $> 16$  mm), close to half (46.7%) were located within 1 DD of the optic nerve. Despite having large tumors, preirradiation visual acuity was 20/40 or better in over one-third of these patients. By 5 years after treatment, however, the majority of patients had experienced severe visual decline (84% had vision worse than 20/200 and 69% had vision worse than counting fingers).

**FIG. 150.8** (A) Patient with a large tumor (largest tumor diameter 21 mm; height 10.5 mm). Before proton irradiation, visual acuity was 20/200. (B) Eight months after treatment, tumor has regressed (height 5.0 mm) and visual acuity is 20/400.

Visual prognosis after proton irradiation for patients with peripapillary and parapapillary tumors is poor, with a 5-year rate of vision loss to worse than 20/200 of 80%. On the other hand, 56% retain vision of counting fingers or better at this time point<sup>35</sup> indicating that proton irradiation is a viable alternative to enucleation for these tumors, which are often unsuitable for plaque radiotherapy (Fig. 150.9).

**FIG. 150.9** (A) Patient with a parapapillary melanoma touching the optic disc. Before proton irradiation, visual acuity was 20/40. (B) Two and a half years after treatment, tumor regression is seen but visual acuity has decreased (20/125). (C) Twenty-four years after proton irradiation, the tumor has regressed (<1.0 mm) and visual acuity is stable (20/100).

Patients with macular tumors also have an elevated risk of visual loss, with a minority of patients (35.5%) retaining at least 20/200 vision by 5 years after proton irradiation. Visual prognosis was better in a subgroup of patients with small and medium-sized tumors; 5-year rates of vision retention of at least 20/200 were 70% in patients who received 50 Gy (RBE) and 44% in patients who received 70 Gy (RBE).<sup>36</sup>

## Complications

Surgical complications from the suturing of tantalum rings have been relatively few. Transient diplopia has been observed for a few weeks after the operation in only a small number of patients since disinsertion of extraocular muscles is never required. In patients

with large tumors, intratumor hemorrhage may occasionally occur as a result of surgical manipulation. Lid dermatitis, madarosis, and epiphora from punctal occlusion have occurred in patients whose eyelids could not be retracted completely from the irradiation field. Corneal epitheliopathy has developed in a small number of cases with large ciliochoroidal melanomas and usually responds to artificial tears. Rubeosis iridis and neovascular glaucoma (NVG), the most serious complications because they may lead to enucleation, are observed in approximately 16% of treated eyes and are usually associated with large tumor volume. In a cohort of 704 patients who received proton therapy for uveal melanoma, the 5-year rate of NVG was 12.7%; subsequently enucleation was required in 4.9% of affected patients.<sup>37</sup> In another study of 127 patients treated by proton irradiation because their tumors were too large for plaque radiotherapy, 34% developed rubeosis during a median follow-up period of 36 months.<sup>38</sup> At MEEI neovascular glaucoma was the primary reason for enucleation in close to one-half of patients (45.9%) with large tumors who required the procedure.

Radiation vasculopathy, consisting of capillary closure, telangiectasis, microaneurysm formation, hemorrhages, exudates, and vascular sheathing, is usually observed in the irradiated area. In macular and paramacular melanomas (<3 mm from the fovea), radiation maculopathy and papillopathy may develop leading to vision loss.<sup>9,32,39</sup> The 5-year cumulative rates of maculopathy and papillopathy in patients with tumors within 4 DD of the macula and/or optic nerve were 64% and 35%, respectively, with increased risk of these complications associated with increased dose to critical structures.<sup>33</sup> The rate of papillopathy was 56.8% at 5 years after proton therapy for tumors located within 1 DD of the optic nerve.<sup>35</sup>

In a study evaluating the natural history of radiation papillopathy, 93 patients with parapapillary melanomas (within 1 DD of the optic nerve and at least 2 DD from the fovea) were followed. By 5 years after proton therapy, radiation papillopathy developed in 81% of cases in which the melanoma abutted the optic nerve and in 67% of cases in which the melanoma was 0.1–1 DD from the optic nerve. Of those who developed papillopathy, 42% retained vision of counting fingers or better and 31% ( $n=13$ )

experienced recovery of visual acuity after an initial loss.<sup>40</sup> These findings challenge the view that irradiation of the optic nerve will inevitably lead to optic neuropathy and total loss of vision.

Significant cataracts may develop in patients with ciliary body involvement or in cases of highly elevated choroidal melanomas in which the lens receives substantial irradiation.<sup>41</sup> The 5- and 10-year cumulative rates of posterior subcapsular cataract (PSC) were 30% and 35%, respectively, in an analysis of more than 2000 patients treated with protons over a 20-year period. Rates were dependent upon the dose to the lens; at 5 years post-therapy, 53% developed cataract when >50% of the lens was irradiated compared with 19% when <10% of the lens was irradiated. For eyes with reasonable visual potential, cataract extraction with intraocular lens implantation may be performed. Approximately 50% of patients undergoing cataract extraction after proton beam irradiation for choroidal melanoma had visual acuity of 20/200 or better after surgery.<sup>42</sup> There was no evidence that cataract extraction increased the risk of metastasis. Removal of a cataract for better observation of the tumor when there is no likelihood of visual improvement, typically due to underlying radiation maculopathy or papillopathy, is usually unnecessary since these tumors can be followed by ultrasonography.

In an effort to reduce the ocular morbidity associated with proton therapy, particularly when tumors are located close to critical structures, a randomized, double-blind dose reduction trial<sup>23</sup> was completed. The experimental dose selected for the trial was 50 CGE. Patients eligible for the trial were at high risk of radiation papillopathy and maculopathy because their tumors were located near the optic nerve or macula. Five years after proton therapy, lower rates of radiation vasculopathy and visual loss were not demonstrated. A modest beneficial effect of lowering the dose was suggested, with lower rates of visual field defects and radiation papillopathy observed in the 50-CGE dose group. For radiation papillopathy, this effect was observed only in the subgroup of patients with tumors located within 1 DD of the optic disc. However, this trial was underpowered to detect subgroup effects. Long-term follow-up (10 years after enrollment) of study subjects did not reveal any late-emerging differences between the two dose

groups. This level of dose reduction (28%) may be inadequate to produce appreciable improvement in functional outcomes, but further reductions could compromise tumor control. Radiation of the tumor with a lower dose became standard at our center for select patients with small or medium tumors located near the optic nerve or fovea in May 2004. Further study to identify possible beneficial effects of a dose reduction, overall and in specific subgroups of patients, is currently underway in this larger cohort of patients.

## Recurrence

Local recurrence after charged-particle irradiation is observed in 2–5%<sup>24–26,43</sup> of patients. In one study<sup>34</sup> of 2069 consecutive patients treated with proton beam irradiation, 45 tumors (2.9%) demonstrated definitive growth, with the earliest occurrence observed 5 months and the latest 11 years after irradiation. Only 23 were marginal recurrences; in the case of anterior tumors involving the ciliary body, marginal recurrences may arise because the pigmented margins of the tumor may be difficult to distinguish from surrounding stroma. Six recurrences were ring melanomas, eight involved extrascleral extension of the tumors, and nine showed vertical growth of the tumors. An additional 15 eyes were enucleated at other centers because tumor growth was suspected. The 15-year probability of local tumor control, based on confirmed and suspected recurrences combined ( $n=60$ ), was 95% (95% CI 93–96%). Similar control rates have been reported in another large series of patients ( $n=2435$ ) treated in Lausanne, Switzerland.<sup>24</sup> Five-year control rates after brachytherapy have been reported to be between 92% and 87%.<sup>44–46</sup> In some cases, eyes with local recurrence can be retreated successfully with repeat proton irradiation<sup>47</sup> or – for cases in which the recurrence is marginal and flat – laser photocoagulation. Proton irradiation has also been used effectively to treat patients with tumor recurrences that were initially treated by other means (e.g., brachytherapy, transpupillary therapy).<sup>48</sup>

A comparison of patients irradiated with iodine-125 plaques versus helium ions revealed a recurrence rate in patients who received brachytherapy that was more than three times that of

patients who received heavy particle irradiation (12-year cumulative rates were 19% and 5%, respectively).<sup>49</sup> Suboptimal plaque positioning<sup>50</sup> in posteriorly located tumors may be one explanation for these poorer outcomes. Proton irradiation may be a better choice of treatment for posteriorly located tumors. A recent study of long-term outcomes after proton irradiation for patients with tumors contiguous to the optic nerve (within 1 DD) revealed a 5-year tumor recurrence rate of 3.3%, virtually identical to the rate seen in patients treated during the same period with tumors farther away from the nerve.<sup>35</sup> In contrast, tumor recurrence was reported in 10% of patients who received brachytherapy for tumors overhanging the disc.<sup>51</sup> The use of notched plaques and other advances in plaque design may improve tumor control in these cases.<sup>51-53</sup>

Achieving tumor control is of particular importance because local recurrence has been shown to elevate the risk of metastasis.<sup>24,26,54</sup> Survival is poorer among patients with local recurrences; 10-year survival rates were 72.6% for patients who experienced tumor control and 47.5% for patients who had tumor regrowth.<sup>24</sup> Similar survival rates were recently reported in an analysis of risk factors for tumor recurrence in 1102 patients treated with proton irradiation.<sup>55</sup> However, it is not clear if recurrence *per se* is actually a risk factor for metastasis or if it is just an indicator of a more aggressive tumor, which is more likely to metastasize.

## Enucleation

The probability of retaining the eye 2 years after proton irradiation is 95%, and the probability is 90% after 5 years.<sup>56</sup> The 10-year rate of eye retention was 89% in a group of 1541 patients treated by proton therapy and followed for a median of 8 years;<sup>54</sup> 137 patients underwent enucleation after radiotherapy for complications ( $n=103$ ) or tumor regrowth ( $n=34$ ). The complication most likely to result in enucleation is neovascular glaucoma. The leading risk factors for enucleation are tumor height,<sup>34,56</sup> proximity of the tumor to critical structures (macula, fovea,<sup>56</sup> optic nerve), tumor diameter, tumor pigmentation, and tumor shape.<sup>34</sup>

Patients with large tumors may experience complications such as

neovascular glaucoma and exudative retinal detachments that often necessitate enucleation. In a series of patients with large tumors (>8 mm in height and >16 mm in diameter) treated with proton irradiation at MEEI, eye loss was experienced by approximately 20% of patients 5 years after treatment. Eye loss rates were higher (23.8%) for tumors located near the optic nerve or fovea (one or both) and lower (9.8%) for tumors located farther away from both structures.

## Metastasis and Survival

Annual rates of melanoma-related mortality are highest 3–6 years after irradiation, but patients continue to be at risk many years after diagnosis. A recent study of very long-term risk of death from melanoma revealed that annual rates do not drop below 1% until 14 years after treatment with proton irradiation.<sup>57</sup> The 5-year cumulative probability of developing metastasis after proton irradiation is approximately 20%.<sup>26,58</sup> The probability of metastatic death at 15 years after proton treatment, using individual risk scores to estimate rates, varies between 5% for patients having the lowest-risk characteristics and 63% for those with the highest-risk characteristics.<sup>34</sup> The liver is primarily involved in 90% of patients with metastasis.<sup>58</sup> In 145 patients who developed metastasis after proton irradiation, median time to metastasis was 2.4 years after irradiation, and most patients were found to be symptomatic before diagnosis.<sup>59</sup> It remains unclear if early diagnosis of metastatic uveal melanoma has an impact on survival. A recent study compared patients who were diagnosed with metastatic uveal melanoma after proton irradiation incidentally or by routine surveillance to those who were diagnosed after developing symptoms. There were no differences between the two groups with regard to median time from diagnosis of primary tumor to metastatic death, suggesting that earlier diagnosis does not have a beneficial effect on survival.<sup>60</sup>

Adjuvant interferon therapy after primary treatment has not been successful in reducing the incidence of metastasis,<sup>61</sup> and therapeutic results for visceral metastatic melanoma are poor. Less than 15% of patients survive to 1 year after the detection of metastasis.<sup>59</sup> In studies of patients who have developed metastasis after

undergoing any type of primary ocular therapy, median survival is 2–9 months.<sup>59,62,63</sup> Significantly longer survival (from time of metastasis diagnosis) occurs among younger patients.<sup>59</sup>

Treatments for metastatic disease largely have been ineffective, and most evaluations of treatments have been done in a nonrandomized setting. Few remissions have been realized with chemoembolization of the liver and immunotherapy with interleukin-2, alone or in combination with other chemotherapeutics, and toxicity is high.<sup>62,64,65</sup> Patients who undergo intrahepatic arterial perfusion have somewhat better outcomes,<sup>66</sup> and a multicenter phase III trial (NCT number 1785316) is currently underway to compare isolated intrahepatic perfusion to best alternative care for patients with isolated liver metastases.<sup>67</sup>

Results from the very few controlled randomized trials completed<sup>68–70</sup> have been disappointing. A preliminary investigation of the efficacy of selumetinib versus chemotherapy (temozolomide or dacarbazine) yielded promising results,<sup>70</sup> but a subsequent phase III randomized, placebo-controlled, double-blind study of selumetinib in combination with dacarbazine versus dacarbazine alone showed no differences in progression-free survival between the treatment groups (<http://www.astrazeneca.com/Media/Press-releases/Article/20150722-astrazeneca-provides-update-on-selumetinib>).

Results of nonrandomized studies comparing survival rates for patients with uveal melanoma after treatment with proton beam irradiation<sup>71</sup> and other forms of radiotherapy<sup>72</sup> with survival rates after enucleation suggest that treatment choice has little effect on survival. Results from the Collaborative Ocular Melanoma Study showed no differences in 5-year rates of death due to histopathologically confirmed metastatic melanoma between patients randomized to undergo enucleation and those who received I-125 brachytherapy (11% vs. 9%, respectively).<sup>1</sup>

## Conclusion

Proton irradiation of uveal melanomas is quite successful in achieving local tumor control. The dose distributions are

particularly advantageous for the treatment of large tumors and tumors located near the optic disc or fovea, with many patients maintaining visual function in the treated eye. Nevertheless, there can be significant ocular morbidity associated with treatment of such cases. Outcomes after treatment of radiation complications with systemic corticosteroids and anticoagulation have been disappointing,<sup>73,74</sup> but preliminary reports of intravitreal triamcinolone,<sup>75</sup> bevacizumab,<sup>76-78</sup> and combination therapy with these compounds<sup>79</sup> suggest some efficacy for radiation maculopathy and papillopathy. Encouraging results have been reported for prophylactic bevacizumab to reduce rubeosis after proton radiation.<sup>80</sup> Among several ongoing trials evaluating pharmacologic agents to reduce radiation complications is a randomized trial evaluating two doses of intravitreal ranibizumab in patients with parapapillary or paramacular tumors treated by proton irradiation.

Another unresolved issue is the optimal fractionation scheme and dose for treatment. Fractionation of the dose is important in optimizing the relative responses of tumor and normal tissue to irradiation. We presently use 70 Gy (RBE) for most cases, and 50 Gy (RBE) in select patients with small and medium-sized tumors near critical structures, delivered in five fractions over a period of 5–10 days. However, the optimal radiation dose that can control a melanoma with minimum ocular morbidity is unknown.

Current results suggest that primary treatment choice has little overall influence on survival in patients with uveal melanoma. It is likely that micrometastasis occurs before any type of ocular treatment has been initiated. Therefore, efforts toward the development of effective adjuvant therapies must continue.

**Conclusions**

## **Introduction**

Choroidal melanoma can be removed by en bloc resection, through a scleral trapdoor (“exoresection”), or with a vitreous cutter passed transretinally (i.e., “endoresection”). Such surgery can be performed as primary treatment or as a salvage procedure after

another form of therapy. (See Video 151.1 online.)

Exoresection of choroidal melanoma is not widely performed, not least because of fears about its safety. Stallard reported two cases in 1966 and advocated partial choroidectomy only as a last resort for patients whose tumors did not regress after radiotherapy or who had poor vision in the fellow eye.<sup>1</sup> In 1973 Foulds challenged the prevailing dogmas about radical surgery and started performing primary exoresection irrespective of the status of the fellow eye.<sup>2</sup> Since then, we have between us performed more than 630 exoresections and 120 endoresections for posterior uveal melanoma.<sup>3-9</sup> Others have also adopted these procedures.<sup>10-17</sup> This chapter describes our surgical techniques, summarizes the results, and discusses the indications in relation to other forms of conservative therapy.

## Exoresection

### Indications and Contraindications

We reserve exoresection for patients who are unlikely to do well with other forms of conservative treatment, such as transpupillary thermotherapy, ruthenium or iodine plaque brachytherapy, and proton beam radiotherapy.

Tumors <6 mm in thickness respond satisfactorily to plaque or proton beam radiotherapy unless they have invaded retina or if they extend close to the optic disc. Radiotherapy of more bulky tumors is associated with a significant complication rate, which increases with time, especially when the tumor extends far anteriorly or posteriorly, or if there is extensive retinal detachment.<sup>18-20</sup> Conversely, large tumor size, anterior location, and the presence of exudative retinal detachment make exoresection less difficult. Two matched group studies have reported that with large tumors, the results are better after exoresection than after iodine plaque radiotherapy.<sup>21,22</sup>

Relative contraindications to local resection include (1) a tumor diameter >18 mm; (2) tumor extension to within a disc diameter (DD) of the optic disc margin; (3) extensive retinal invasion or any retinal perforation; (4) extraocular extension; (5) more than 2 clock-

hours of ciliary body or angle involvement; and (6) general health precluding hypotensive anesthesia. If, however, the patient has poor vision in the fellow eye, or if enucleation is refused, then local resection can be performed, with special measures being taken to deal with the increased surgical difficulties. Absolute contraindications include diffuse melanoma and optic nerve invasion. Old age is not in itself a contraindication because hemorrhage is arrested at a higher blood pressure than is the case with young subjects, making profound hypotension unnecessary. It is possible to perform exoresection in children.<sup>23</sup>

## Preoperative Workup

It is essential to identify adverse factors, such as retinal invasion by the tumor, indistinct tumor margins, and any systemic contraindications to hypotensive anesthesia, including ischemic heart disease, cerebrovascular insufficiency, and significant renal or respiratory impairment. The advantages and disadvantages of local excision in relation to other forms of therapy are discussed with the patient, with all patients receiving an audio recording of this conversation.

## Surgical Technique

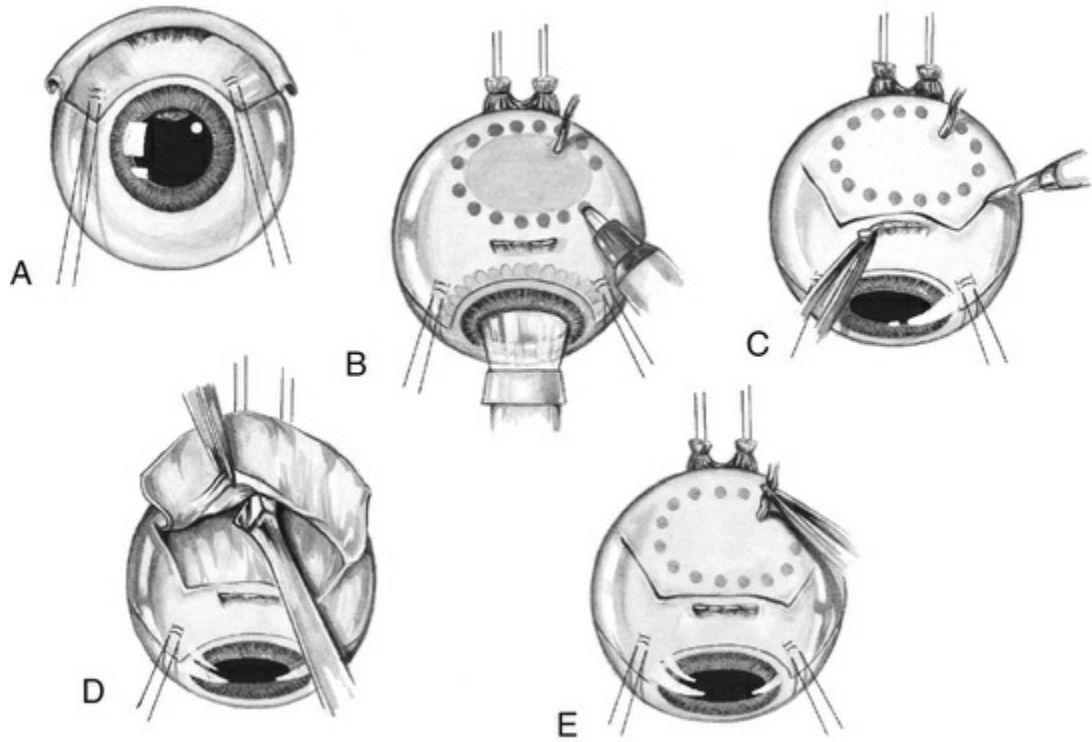

### Preparation

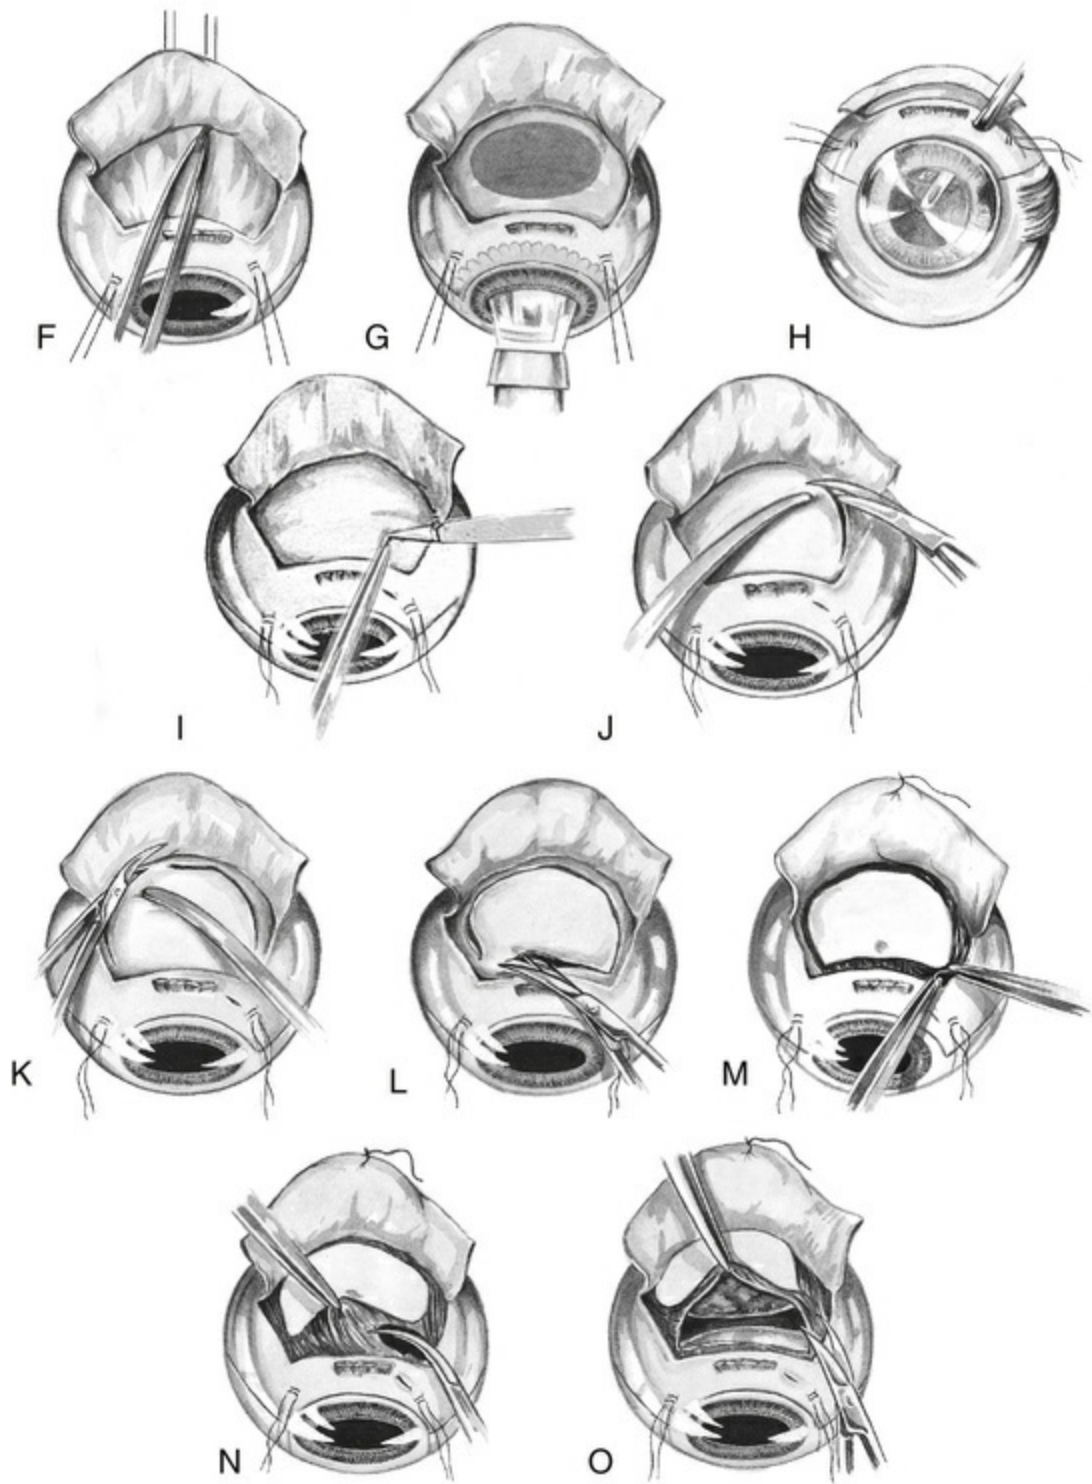

As with other intraocular surgery, the skin and conjunctiva are cleaned with antiseptic solution (e.g., povidone–iodine) and the pupil is dilated.

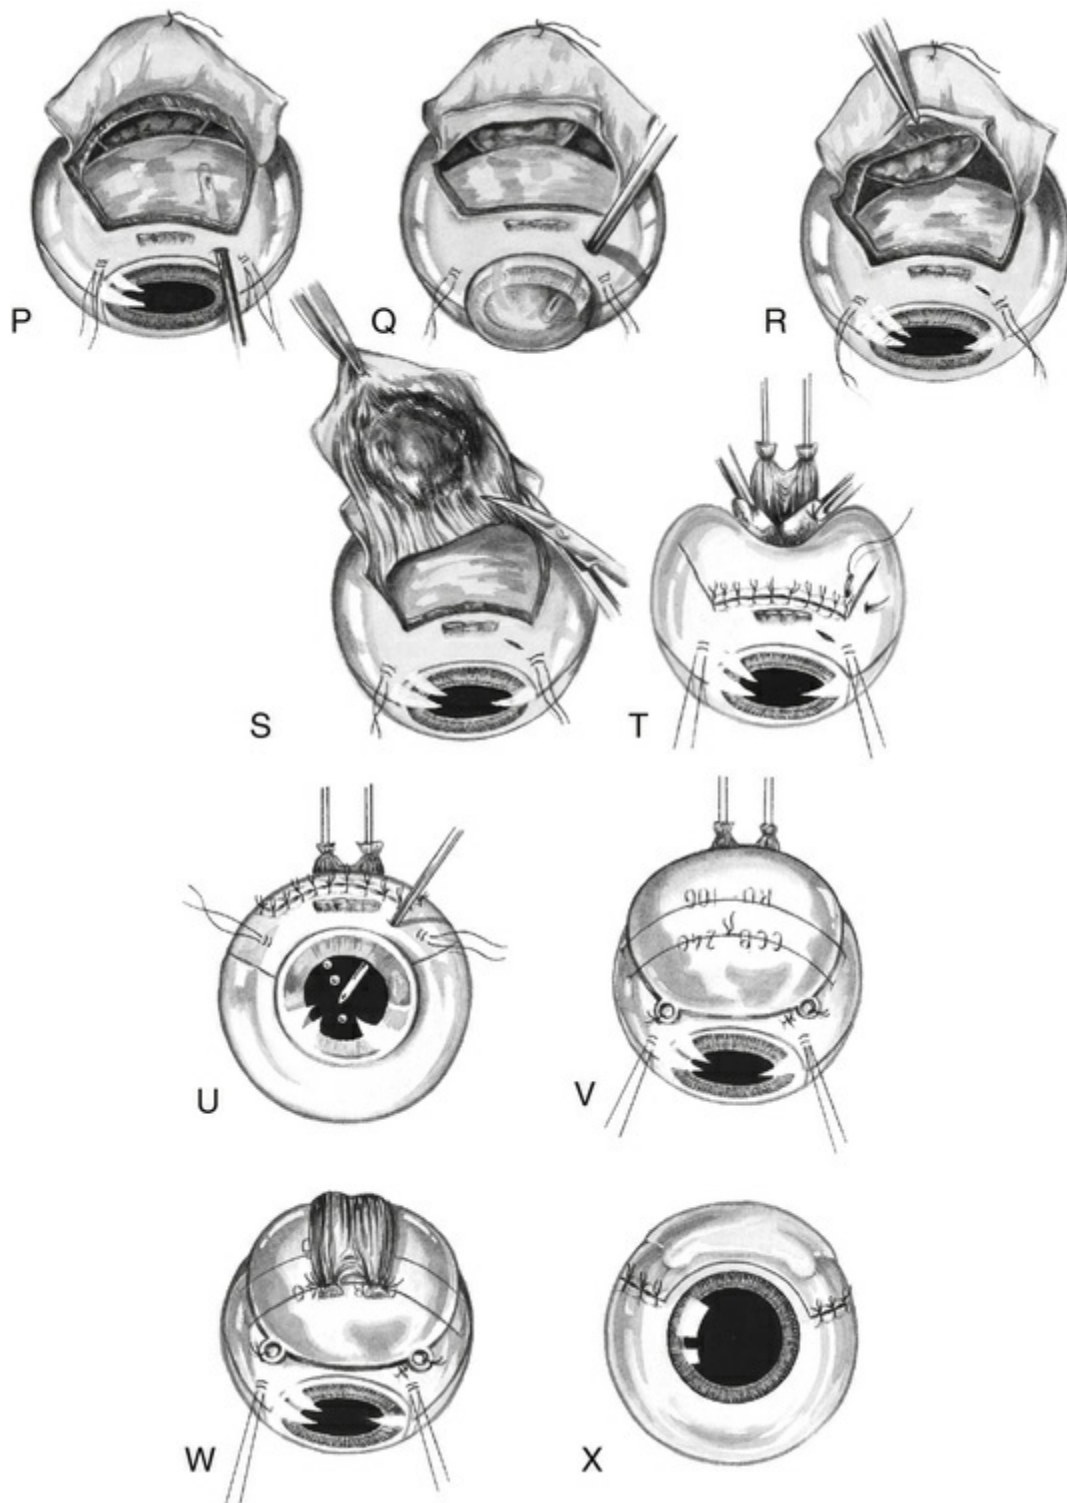

### Exposure

The lashes are secured away from the eye with steristrips. The eyelids are retracted using both a wire speculum and traction sutures. The ocular surface is kept moist with 1.5% methylcellulose solution. A 180° limbal conjunctival peritomy is made. The episclera is removed with a No. 15 Bard Parker scalpel. Intervening extraocular muscles are disinserted, leaving a 1-mm tendon stump to aid reinsertion. Two scleral traction sutures (i.e., 5-0 braided polyester) are passed 4 mm posterior to the limbus and clipped

with hemostat forceps (Fig. 151.1A). The tumor margins are identified by transillumination and marked on the sclera with a felt-tipped pen (Fig. 151.1B).

**FIG. 151.1** Technique of exoresection. (A) Conjunctival incision and placement of bridle sutures. (B) Transpupillary transillumination with demarcation of tumor margins with a pen. (C) Partial-thickness scleral incisions for creation of a scleral flap. (D) Lamellar scleral dissection. (E) Closure of vortex vein behind eye with diathermy. (F) Closure of vortex vein within sclera with diathermy. (G) Confirmation of adequacy of

scleral flap by transpupillary transillumination. (H) Ocular decompression. (I) Scleral buttonhole lateral to tumor. (J) Scleral incision lateral to tumor. (K) Scleral incision posterior to tumor. (L) Anterior scleral incision. (M) Choroidal opening. (N) Choroidal incision anterior to tumor. (O) Choroidal incision lateral to tumor. (P) Further vitrectomy is performed if ocular decompression is inadequate. (Q) Further vitrectomy with corneal contact lens. (R) The retina should separate from the choroid to facilitate dissection. (S) Choroidal incision posterior to tumor. (T) Scleral suturing with traction on bridle sutures and ocular indentation to increase intraocular pressure. (U) Intravitreal injection of fluid. (V) Placement of radioactive plaque. (W) Reinsertion of extraocular muscles. (X) Closure of conjunctiva.

## Lamellar Scleral Dissection

A posteriorly hinged lamellar scleral flap is fashioned. It is polyhedral, rather than circular, to facilitate good wound edge apposition during closure (Fig. 151.1C). The scleral flap should clear the apparent tumor margins by about 5 mm (Fig. 151.1G). By making the flap wider posteriorly, it is possible to reduce the length of the lateral incisions, facilitating closure. The flap should be about 80% of the scleral thickness. Any inadvertent buttonholes in the superficial flap are immediately closed with a purse-string 8-0 nylon suture. Any buttonholes in the deep sclera are sutured to prevent prolapse of choroid or tumor.

The flap is created using a feather blade for the initial scleral incisions and a Desmarres scarifier for lamellar scleral dissection (Fig. 151.1D).

To avoid troublesome hemorrhage, any vortex veins overlying the scleral flap are cauterized before being divided, applying bipolar diathermy both extraocularly (Fig. 151.1E) and to the intrascleral portion of the vein after cautiously exposing as much of the vessel as possible (Fig. 151.1F). Long ciliary vessels overlying the scleral flap are treated similarly. Gentle bipolar cautery of some of the short ciliary vessels adjacent to the optic nerve further reduces hemorrhage.

## Ocular Decompression

Partial ocular decompression by limited pars plana vitrectomy facilitates local excision by reducing retinal bulging through the scleral window and improving access to the posterior uvea.

Vitrectomy can be performed before, during, and/or after scleral flap dissection.

If vitrectomy is delayed until the scleral flap is prepared, three-port vitrectomy with infusion is unnecessary. Vitrectomy can be performed through a single sclerotomy using illumination from the operating microscope and a disposable vitrectomy contact lens (Fig. 151.1H).

During creation of any vitrectomy sclerotomies, the posterior segment should be kept in view to avoid damaging the retina overlying the tumor.

The vitreous cortex should be preserved so that as soon as the tumor is excised, the retina can be repositioned by injecting fluid into the vitreous cavity; otherwise, in the presence of a large scleral opening and a defect at the pars plana, it may be difficult to flatten the retina after tumor resection.

## Deep Scleral Incision

Two small buttonhole incisions are made in the deep sclera about 2 mm inside the superficial scleral incision anterolateral to the tumor (Fig. 151.1I). To avoid damaging choroid, the sclera is pinched with fine-toothed microforceps to create a fold, which is then shaved with a knife until perforation occurs. This scleral incision is extended around the tumor with blunt-tipped corneoscleral scissors (Figs. 151.1J–K). The deep scleral incision is kept 2 mm inside the superficial scleral incisions to create a stepped wound edge, which facilitates closure (Fig. 151.1L). To prevent excessive bulging of intraocular contents, the lateral and posterior scleral incisions are completed before the anterior incision is made.

The tumor appears different from healthy choroid so that it is possible to define its margins by direct inspection. Once the deep scleral incisions are made, the anterior margin of the deep scleral lamella is marked with a notch to enable the pathologist to orient the excised specimen.

## Tumor Excision

Tumor excision is commenced after ensuring the eye is soft, if necessary aspirating further fluid from the vitreous cavity and removing the hemostat forceps from the traction sutures. An eye basket or Flieringa ring is not necessary. Bipolar cauterization of the choroid around the tumor may reduce hemorrhage, but must be very gentle as it may weaken the underlying retina, increasing the risk of breaks.

The subretinal space is entered, preferably at a site where the retina is detached (Fig. 151.1M). This is done by holding the choroid with two pairs of ribbed (not toothed) microforceps and moving them apart to tear the uveal tissue.

The anterior part of the tumor is lifted from the subjacent retina with toothed forceps applied to the deep scleral lamella, which usually remains firmly adherent to the tumor. If the sclera separates from the tumor, it is reattached to the tumor with tissue glue so as to avoid the need for cryoextraction, which is cumbersome.

Usually, the choroid is divided in front of the tumor (Fig. 151.1N), then laterally (Fig. 151.1O), and finally posteriorly, using blunt-tipped corneoscleral scissors. If there is excessive retinal bulging, further vitrectomy is performed, with the vitrector being viewed through the retina (Fig. 151.1P) or the pupil (Fig. 151.1Q). If ocular decompression is adequate, the retina should fall away from the tumor so that a space appears between the retina and the normal choroid around the tumor margins (Fig. 151.1R). This allows the uveal tissue posterior to the tumor to be divided with the corneoscleral scissors (Fig. 151.1S). Despite the systemic hypotension, there is usually some hemorrhage, which must be mopped away before clots form, because these are difficult to remove.

As soon as the tumor is excised, the instruments are exchanged for a fresh set to prevent tumor seeding. At the earliest opportunity the intravitreal pressure is increased until the retina bulges slightly in the scleral window so that there is no potential space in which a subretinal hematoma can form. This is achieved by exerting traction on the bridle sutures and by compressing the eye with sponges placed behind the eye, posterior to the scleral window (Fig. 151.1T).

## Scleral Closure

The corners of the flap are sutured first, followed by the anterior margin and finally the lateral margins. Interrupted 8-0 nylon sutures are placed about 2 mm apart. As soon as the suturing of the flap is complete, the globe is reformed by injecting balanced salt solution intravitreally, either using the three-way tap, if an infusion cannula is present, or through a 25-gauge needle attached to a syringe (Fig. 151.1U). Gas tamponade is no longer considered useful, but 2 mL of air is kept in the syringe when injecting fluid, because its compressibility prevents a sudden rise in intraocular pressure, which might reopen the wound.

## Adjunctive Brachytherapy

Adjunctive plaque radiotherapy is routinely applied, delivering a dose of approximately 100 Gy to a depth of 1–2 mm. We favor a 25-mm ruthenium plaque because of the limited range of beta irradiation, the convenience of a long half-life, and the thin shape of the implant, which facilitates positioning over the site of the excised tumor (Fig. 151.1V). If the superficial flap has inadvertently been buttonholed, or if cyclectomy has been performed, this brachytherapy is delayed by 1 month.

## Eye Closure

The muscles are resutured to their original insertions with 5-0 braided polyglycolic acid sutures (Fig. 151.1W). When the muscle insertion is located on the scleral flap the muscle stump is left long to avoid the need for placing the suture in the sclera. To compensate for any muscle shortening, the distance from the suture knots to the limbus is measured before the muscle tendon is divided and also at the time of reinsertion so that a sling is used if necessary.

The conjunctiva is closed with 7-0 braided polyglactin sutures (Fig. 151.1X). Antibiotics, mydriatics, and steroids are given in the usual fashion. The entire procedure usually takes between 2 and 3 hours.

## Variations in Technique

## **Ciliary Body Involvement**

If a choroidal tumor involves the ciliary body, the anterior margin of the superficial scleral flap is placed 1 mm posterior to the limbus. A half-thickness incision is then made in the deep sclera, about 2 mm posterior to the superficial incision, and the deep sclera is split into another two layers by lamellar dissection, which extends anteriorly into cornea. This scleral step ensures that the anterior wound edge is watertight. This is especially important if adjunctive plaque radiotherapy is administered.

The chances of developing retinal detachment are greatly reduced by conserving as much of the ciliary epithelium as possible. This is achieved by perforating choroid posterior to the ora serrata and then using closed, blunt-tipped scissors to separate ciliary epithelium from uvea by blunt dissection before cutting the uveal tissue with scissors.

## **Retinal Adhesion**

Problematic adhesion between tumor and retina is more common with relatively thick tumors.<sup>8</sup> Adherent retina can often be separated from the tumor by blunt dissection of the tumor surface with a No. 15 Bard Parker scalpel, about 1–2 mm away from the apparent line of retinal adhesion, to divide invisible strands of tissue joining retina to tumor. If this fails, the tumor has probably invaded the retina. In this case, our preferred course of action is to top-slice the tumor with the scalpel, leaving the intraretinal portion in situ and treating it with radiotherapy. Another option is to excise the tumor completely, together with the invaded retina, dealing with the retinal defect after closing the sclera. Any retinal defect is managed by complete pars plana vitrectomy, subretinal hemorrhage aspiration, endolaser photocoagulation, and silicone oil tamponade, with these procedures preferably performed as soon as possible, immediately after reforming the eye with balanced salt solution. Our results show that these measures are highly successful at preventing retinal detachment.<sup>8</sup>

## **Extraocular Extension**

Previously, if a small tumor nodule extended transsclerally, it was

excised together with the intraocular tumor and a surround of full-thickness sclera, closing the defect with a lamellar scleral graft from the same eye. Today, we would more conveniently cauterize the extraocular tumor with bipolar diathermy or excise it en bloc with a thin layer of superficial sclera, relying on brachytherapy to sterilize any surviving tumor.

## **Exoresection Without Profound Hypotensive Anesthesia**

Our experience with exoresection without profound systemic hypotension is limited. If resection is done under normotensive anesthesia, meticulous bipolar cautery should be applied as soon as any bleeding point develops in the sclera. If possible, the short posterior ciliary arteries and the long posterior ciliary artery should be cauterized before closing any vortex veins, to prevent what in one patient seemed to be severe choroidal congestion and possibly an expulsive hemorrhage, with marked retinal bulging through the scleral window, despite repeated vitrectomy. Cold water and epinephrine drops may diminish choroidal hemorrhage in addition to bipolar cautery, which should be applied with minimal energy to avoid damaging the retina. Swabbing may not be sufficient to control hemorrhage so that a mini-suction device should be available to aspirate blood as it collects in the subretinal space during tumor excision.

## **Postoperative Management**

In the immediate postoperative period, the patient is positioned so that the coloboma is situated below the macula, thereby preventing any subretinal hemorrhage from gravitating toward the fovea. Residual subretinal fluid from the preoperative exudative retinal detachment generally resorbs spontaneously within a few days.

Routine medications include topical antibiotics, steroids, and mydriatics. Systemic antibiotics can be administered as an intraoperative bolus or postoperatively. Oral steroids seem to reduce postoperative uveitis but have not been evaluated in a randomized fashion.

Patients are discharged home 1 day after the plaque removal,

which is usually 1 or 2 days after local resection. They are reassessed after 1 and 4 weeks, and then followed as with other treatments.

## Anesthesia

Intraoperative hemorrhage is reduced by profound hypotensive anesthesia.<sup>24</sup> This lowers the systolic blood pressure to approximately 40–50 mmHg for about 60 minutes, from the time when ocular decompression is performed to the moment when the intraocular pressure is increased by intravitreal injection after scleral flap closure.

Cerebral function is monitored with a continuous electroencephalogram. The blood pressure is measured continuously with an intraarterial line in the radial artery. Standard procedures such as pulse oximetry and electrocardiographic monitoring are performed. Antithrombotic stockings are used postoperatively, and early mobilization is encouraged. Complications related to systemic hypotension are rare.

## Outcomes

### Visual Acuity

In 2011 the authors audited 112 exoresections performed in the previous 10 years (unpublished data). The tumors had a median diameter of 15.3 mm (range 8.9–22.4) and a median thickness of 8.5 mm, with 41% involving ciliary body and 16% extending to within 3 mm of the optic disc or fovea. The successful resections included several challenging cases, such as a patient operated on without any hypotensive anesthesia (because she had anemia due to thalassemia) and another patient who had an advanced tumor with total funnel retinal detachment touching the lens and an intraocular pressure of 44 mmHg. At the close of the study, 88% of eyes were retained, with 58% having visual acuity of 20/200 or better and 30% having 20/40 or better (Fig. 151.2). In a previous investigation, we showed that the most significant preoperative factors for predicting retention of good vision (20/40 or better) were medial tumor location ( $p=.002$ ) and distance of more than 1 DD between the

tumor and the optic disc or fovea ( $p=.01$ ).<sup>4</sup>

**FIG. 151.2** Inferonasal choroidal melanoma of the left eye of a 45-year-old man, having a largest basal diameter of 15 mm and a thickness of 11 mm before exoresection with adjunctive brachytherapy (A) and 6 months afterward, when the visual acuity was 20/40 (B). This procedure was selected because any form of radiotherapy would probably have resulted in persistent exudative retinal detachment and eyelid damage with permanent epiphora. The tumor was of spindle-cell type with no chromosome 3 loss so that the survival probability was very good.

## Local Tumor Control

In our 2011 audit there were no patients with visible residual tumor at the end of the resection procedure. Recurrent tumor developed in 12 patients, after a median of 2.4 years (range 0.6–3.8). Adjunctive brachytherapy seems effective at preventing local tumor recurrences in the irradiated field; however, there have been a few recurrences in nonirradiated areas, that is, in distant parts of the uvea or if adequate coverage of the resection area by the plaque could not be achieved, because the tumor had an irregular shape, or because it extended close to the optic disc, or because the plaque was not large enough to treat a sufficiently wide surround of apparently healthy choroid. We now use a 25-mm plaque instead of

a 20-mm plaque. In a previous study of 286 resections performed before the introduction of adjunctive brachytherapy, we showed by Cox multivariate analysis that the predictive factors for recurrent tumor are posterior extension to within a disc diameter of disc or fovea ( $p=.002$ ), presence of epithelioid cells ( $p=.002$ ), and tumor diameter of 16 mm or more ( $p=.019$ ). Histologic examination of clearance margins was unreliable.<sup>6</sup>

Local tumor recurrence can arise at the margin of the surgical coloboma as an indistinct gray, brown, or white swelling. Rarely, the tumor recurs within the coloboma as a result of intraretinal or intrascleral tumor invasion. Exceptionally, a satellite lesion develops in a distant part of the choroid.<sup>25</sup> Noncontiguous recurrences have also been seen after plaque radiotherapy.<sup>26</sup> Residual and recurrent tumors need to be distinguished from reactive pigment epithelial hyperplasia and organized subretinal hematomas. Sequential fundus photography and optical coherence tomography are invaluable for distinguishing tumor from other conditions. If there is any doubt about the diagnosis, the suspicious lesion should be ablated by transpupillary thermotherapy as a precautionary measure.

Definite residual or recurrent tumor is best treated with plaque or proton beam radiotherapy, unless very small or situated close to the optic disc or fovea, in which case transpupillary thermotherapy can be attempted (Fig. 151.3). Failure to detect and treat a recurrent tumor effectively can result in extraocular tumor extension or optic disc involvement so that enucleation becomes necessary.

**FIG. 151.3** Left fundus of a 67-year-old woman (A) soon after exoresection, with apparently complete

resection in 1989 and (B) 9 months later, showing a local tumor recurrence from a microscopic deposit. Histologic assessment of surgical clearance is unreliable, so adjunctive radiotherapy is now applied routinely.

## **Retinal Detachment**

Before the introduction of ocular decompression, retinal tears sometimes occurred because of retinal prolapse during tumor excision. Today, retinal tears occur almost exclusively when attempting to separate tumor from adherent retina. Retinal breaks can usually be identified immediately and rarely result in retinal detachment if adequate vitreoretinal surgery is performed promptly. Our 2011 audit showed the rate of retinal detachment to be 9%. We previously demonstrated retinal detachment to correlate with tumor thickness.<sup>7</sup>

Postoperative vitreous hemorrhage indicates the presence of a retinal tear and hence a high risk of retinal detachment, so appropriate vitreoretinal surgery should be performed without delay, before proliferative vitreoretinopathy develops.

Although it might seem useful to apply preoperative retinopexy, this is rarely possible because of large tumor bulk or extensive serous retinal detachment.

## **Other Complications**

Macular function is usually retained unless there is direct foveal involvement by the tumor or preoperative retinal detachment. Vision may be reduced if the excision line is close to the fovea or if a choroidal tear occurs as a result of excessive traction on the tumor during resection. A macular disciform lesion can occur from choroidal neovascularization arising at the edge of the surgical coloboma, if this extends far posteriorly. Cataract is uncommon, unless it was present preoperatively, for example, due to a ciliary body tumor; it tends to occur only in the presence of long-standing retinal detachment or after the use of intraocular silicone oil. Any postoperative diplopia usually resolves spontaneously; extraocular muscle surgery is rarely required.

Adjunctive brachytherapy may cause (1) wound dehiscence, which is prevented by the use of nonabsorbable sutures, and (2) cyclodialysis with hypotony, which is prevented by delaying radiotherapy by a month if cyclectomy has been performed. Optic neuropathy and radiation maculopathy can be avoided by not positioning the plaque close to disc or macula. Adjunctive brachytherapy reduces complications previously caused by wide surgical resection margins, which are no longer necessary. The greatest impact of such minimal surgical clearance has been with ciliochoroidal tumors, which are now excised without the need for broad iridectomy.

## **Metastatic Death**

Nonrandomized, matched group studies suggest that the incidence of metastatic disease after local excision of uveal melanoma is not significantly different from that after enucleation<sup>3</sup> or plaque brachytherapy.<sup>27</sup>

In a series of 332 patients treated by transscleral local resection before 1996, we showed the probability of metastatic death to correlate with epithelioid cellularity and large tumor diameter.<sup>5</sup> Although highly significant statistically, these correlations had little clinical relevance because they provided only an approximate indication of the prognosis as far as an individual patient was concerned. In 1996, Prescher et al. showed loss of chromosome 3 (i.e., monosomy 3) within uveal melanoma cells to be highly predictive of metastatic disease and death.<sup>28</sup> Since 1999 we have therefore determined chromosome 3 status as a routine service, first using fluorescent in situ hybridization (FISH),<sup>29</sup> then by multiplex ligation-dependent probe amplification.<sup>30</sup> At the University of California San Francisco, we now perform next generation sequencing, which provides information on more than 500 selected genes. We developed and validated an online tool for predicting survival according to clinical stage, histologic grade, and chromosome 3 loss, also taking the patient's age and sex into account ([www.ocularmelanomaonline.org](http://www.ocularmelanomaonline.org)).<sup>31</sup> These genetic studies have enabled us to reassure those with an excellent prognosis for survival, while referring high-risk patients to an oncologist for specialized care. Local resection provides large specimens for

prognostic studies and in the future may be useful for selecting systemic treatment or for developing vaccines or other forms of targeted therapy.

Since metastatic disease occurs almost exclusively with melanomas showing chromosome 3 loss, and since almost all such tumors prove fatal, it would seem the patient's survival prognosis is already sealed by the time the local resection is performed. If local resection has less effect on survival than previously believed, then any intuitive concerns about the surgical manipulations inducing or encouraging metastatic spread might prove to have been exaggerated. Further studies are required and these will require molecular tumor characterization.

## Endoresection

The main objectives of primary endoresection of choroidal melanoma are to avoid optic neuropathy and maculopathy after radiotherapy,<sup>32,33</sup> and local tumor recurrence and extraocular extension after transpupillary thermotherapy.<sup>34</sup>

## Indications and Contraindications

We currently undertake this surgery as a primary procedure only if (1) radiotherapy is unlikely to conserve useful vision, because the tumor has perforated retina or extends close to optic disc, and (2) the patient is highly motivated to retain vision and understands the controversial nature of this operation.

## Surgical Technique

Briefly, the technique involves the following steps: (1) pars plana vitrectomy with a 20- or 23-gauge vitreous cutter; (2) the creation of a retinotomy over the tumor; (3) piecemeal tumor removal; (4) endolaser to the margins and bed of the coloboma; (5) perfluorocarbon liquid injection to flatten the retina; (6) endolaser retinopexy to attach retina around the coloboma; (7) endolaser photocoagulation to the entire scleral bed, to destroy any residual tumor; (8) perfluorocarbon–silicone exchange to maintain retinal

flattening and to prevent postoperative hemorrhage; (9) 360° scleral indentation with cryotherapy to any entry site tears; and (10) cryotherapy to the sclerotomies, in case of unrecognized tumor seeding.<sup>9</sup> Following a report of fatal air embolism during endoresection, we perform direct heavy liquid-silicone oil exchange, avoiding fluid-air exchange.<sup>35</sup> Recent developments include the use of endoscopic vitrectomy in some cases, and bimanual surgery with chandelier endoillumination. Adjunctive ruthenium plaque radiotherapy can be administered either in all cases or in selected cases at a later date if histologic or genetic studies indicate a high grade of malignancy.

## Outcomes

Endoresection techniques have improved since our initial publication in 1998.<sup>8</sup> Outcomes depend largely on tumor location (Figs. 151.4 and 151.5). We recently analyzed our results after 71 procedures performed between 1996 and 2010.<sup>9</sup> The follow-up had a median of 4.1 years, exceeding 4 years in 49% of patients. The tumors had a mean basal diameter of 9.5 mm and a mean thickness of 4.4 mm, abutting the optic disc in 34%, extending to within 2 DD of the optic disc in another 31% of patients. The 68 eyes that were retained had visual acuity better than 20/40 in 13% and better than 20/100 in 31%. Rhegmatogenous retinal detachment occurred in 22% of eyes, and local tumor recurrence occurred in two patients (3%) at the margins of the coloboma in both cases. No patients developed seeding. Five patients (9%) died of metastatic disease.

**FIG. 151.4** A 37-year-old woman treated by endoresection. (A) Left eye before treatment, with visual acuity of 20/20 and a 10.1 × 6.5 × 2.8 mm melanoma extending close to the optic disc. (B) Fundus appearance 10 years later, with no visible tumor and visual acuity of 20/30. The patient was healthy with no sign of recurrent disease.

**FIG. 151.5** Endoresection of a large juxtapapillary choroidal melanoma in the left eye of a 44-year-old man, performed using perfluorocarbon liquid instead of air to flatten the retina and endoscopy when the media became opaque. (A) Preoperative color photograph showing the tumor overhanging the optic disc. (B) Ultrasound scan showing the tumor to have a thickness of 13.5 mm but with basal dimensions of only 6 mm by 9 mm. (C) Postoperative photograph showing the surgical coloboma and a normal macula. Seventeen months postoperatively, there was no sign of local tumor recurrence and the visual acuity was 20/30.

Mortality after endoresection seems similar to that after other

treatment modalities. Large randomized studies would be required to reveal any differences, and these are not logistically possible. The considerations discussed in the section on exoresection apply to endoresection (see above).

As with other forms of therapy, local recurrence after endoresection tends to occur from untreated residual tumor in the adjacent choroid and in sclera, and such recurrent tumor can extend extraocularly if not treated promptly.<sup>36</sup> So far, we have not seen widespread intraocular recurrences from intraoperative tumor seeding. In one patient an untreated marginal recurrence spread through the retinal defect to invade the vitreous cavity.<sup>37</sup> This patient, who lived far from our center, had been discharged back to her retinal surgeon, who was unable to monitor the fundus because of cataract. Such spread would not have occurred if the eye had been enucleated as soon as ophthalmoscopy was no longer possible, a policy we have always followed after all types of conservative treatment. Another patient developed subconjunctival seeding, a complication we have also seen with tumor biopsy.<sup>38</sup> Several authors precede endoresection with radiotherapy to reduce the risk of iatrogenic tumor seeding.<sup>13,14</sup> Our impression is that such seeding is rare, at least in patients with a small melanoma, so that many patients must be developing radiation-induced complications unnecessarily. There would seem to be scope for randomized studies.

When the tumor extends close to fovea, visual loss can occur if fibrosis from the margin of the coloboma distorts the retina. Other possible complications of endoresection include silicone oil-induced complications; entry-site tears; submacular hemorrhage; and endophthalmitis. Despite a large retinotomy, proliferative vitreoretinopathy does not develop unless rhegmatogenous retinal detachment has occurred.

## **Secondary Local Resection for “Toxic Tumor” After Radiotherapy**

Neovascular glaucoma is a common problem after radiotherapy of uveal melanoma, especially with large tumors. Some have

suggested this complication is due to extensive irradiation of healthy ocular tissues.<sup>39</sup> However, we believe this complication is, at least in part, caused by the presence of a large volume of irradiated tumor, either because it becomes ischemic or because it causes extensive retinal detachment, or both (i.e., “toxic tumor syndrome”). We have successfully treated these complications in several patients by performing exoresection or endoresection of the toxic tumor.<sup>40</sup> Fig. 151.6 shows the left eye of a 75-year-old man, who had a choroidal melanoma measuring 13.2 × 10.5 mm in diameter with a thickness of 9.3 mm in the left eye. The patient was keen to retain the eye because the right eye was amblyopic with visual acuity of 20/100. He was treated with proton beam radiotherapy because he was on anticoagulation for cardiac arrhythmia. The irradiated eye developed exudative retinal detachment with reduction of vision to 20/100 and neovascular glaucoma with an intraocular pressure of 46 mmHg. Exoresection was performed with minimal hypotensive anesthesia. The retinal detachment resolved within a day. The iris neovascularization regressed within a month, and 24 months after the resection the intraocular pressure was normal without topical medications. Some 8 years after the surgery, the patient was well and when tested with a LogMAR chart was able to see 66 letters with the affected eye and 60 letters with the fellow eye (Fig. 151.6).

**FIG. 151.6** Resolution of “toxic tumor syndrome” after secondary exoresection of a choroidal melanoma. (A) Ocular echography 15 months after proton beam radiotherapy, when the eye developed visual loss,

exudative retinal detachment, and neovascular glaucoma with an intraocular pressure of 46 mmHg. (B) Fundus appearance after secondary exoresection, which achieved resolution of retinal detachment and neovascular glaucoma.

Local resection is also effective for recurrent tumor after other forms of therapy, selecting exoresection for large anterior tumors and endoresection for smaller, posterior tumors (Fig. 151.7).

**FIG. 151.7** Recurrent choroidal melanoma in the right eye of a 52-year-old woman after brachytherapy at another center. The visual acuity was 20/40. The left eye had previously been enucleated after an accident. (A) Preoperative photograph showing the tumor (16 × 16 × 10 mm) overhanging the optic disc. (B) Fundus appearance 4 months postoperatively, when the visual acuity was 20/60. The patient retained useful vision until she died of metastatic disease. The recurrent tumor had shown epithelioid cells and chromosome 3 loss.

## Conclusions

Exoresection and endoresection are useful both as primary treatment for choroidal melanoma, when other forms of therapy are unlikely to conserve useful vision, and as salvage therapy when other methods have failed. It would therefore be ideal if surgical

resection were included in the therapeutic repertoire of large oncology centers. The tumor tissue provided by local resection is already useful in enhancing prognostication and planning patient care. In the future, such tissue will probably become more valuable if large tumor samples are required for individualizing systemic therapy, as is already happening with other cancers.

Insights from molecular biology suggest that fears about iatrogenic tumor dissemination to other parts of the body are exaggerated. Surgical and anesthetic techniques have advanced considerably in recent years, so that good results are now achieved by experienced surgeons. For these reasons, the greatest obstacle still preventing local resection from being performed in greater numbers is the surgical expertise required for such complex surgery. We hope this chapter will make it easier for local resection of choroidal melanomas to be adopted more widely.

### Introduction

Photocoagulation, as introduced by Meyer-Schwickerath in 1949,<sup>1</sup> was among the first eye-salvaging treatment methods for choroidal melanomas and the first to make use of a light source. The armamentarium of eye salvaging treatment modalities for choroidal melanomas has significantly enlarged since then, including radiation techniques (brachytherapy, teletherapy with protons, and stereotactic conformal radiation with photons) and surgical excision (transscleral or transretinal resection), as did the techniques and light sources for laser treatment of choroidal melanomas.

Transpupillary thermotherapy making use of infrared lasers at a subcoagulation level was introduced in 1992 by Journée-de Korver and Oosterhuis<sup>2</sup> and was utilized for primary treatment of small uveal melanomas. Other laser techniques like photodynamic treatment of uveal melanomas were evaluated experimentally and in small case series.<sup>3</sup> This chapter discusses the current role of laser treatment in the management of choroidal melanomas in relation to the alternative treatment methods currently available.

### Laser Techniques Available for the Treatment of Intraocular Tumors

As in other fields of ophthalmology, lasers may be used for the treatment of uveal melanomas for thermal (coagulative or noncoagulative) and nonthermal treatment techniques.

By convention, photocoagulation is considered to be laser treatment at a temperature level of more than 75°C.

Photocoagulation attempts to destroy a uveal tumor with light from a high-intensity light source, which originally was not a laser but a xenon arc light.<sup>4</sup>

Noncoagulative laser treatment techniques include low-power long-exposure treatment techniques making use of a conventional argon blue–green laser or infrared laser. Depending on the

wavelength of the laser used, the lesions are located deeper in the choroid when infrared or near-infrared lasers are used, and lesions created by argon blue–green lasers do not extend 1 mm in size while infrared lasers may result in a depth of tumor necrosis of several millimeters.<sup>5</sup>

Nonthermal laser techniques include photodynamic treatment (PDT) of intraocular tumors making use of the cytotoxic effect of singlet oxygen radicals by photosensitizers when activated by visible light with a defined wavelength. PDT eventually results in photothrombosis of pathologic vessels. Photodynamic treatment was initially developed for the treatment of choroidal neovascularization in age-related macular degeneration and has been used effectively in the treatment of choroidal hemangioma.

## Photocoagulation

Photocoagulation treatment is started by circumvallating the tumor with intensive laser photocoagulation lesions, resulting in an atrophic scar followed by direct treatment of the tumor with high-intensity burns, including disruption of the tumor tissue and occasionally appearance of gas bubbles inside the target tissue. As expected, this technique may result in numerous treatment-related retinal complications, including retinal breaks, epiretinal membrane formation vascular, occlusion, and traction retinal detachment. Only small tumors can be treated, and even in this subgroup of small tumors, a relatively high recurrence rate of uveal melanomas after photocoagulation treatment has been reported. In particular, extrascleral extension of the melanoma may occur, growing underneath the fibrous scar overlying the tumor remnants. Consequently, photocoagulation treatment as sole treatment of a uveal melanoma has been abandoned in most centers.<sup>6</sup>

## Transpupillary Thermotherapy

### Technique

The term “transpupillary thermotherapy” (TTT) was introduced by Journée-de Korver<sup>2</sup> to describe a technique in which a near-infrared

or infrared light source for long-term exposure laser treatment of uveal melanomas is used. There is a controversial discussion in the literature on whether the word “thermotherapy” is appropriate or whether this treatment technique should be regarded as long-exposure subthreshold photocoagulation using a long-wavelength light source, since a whitish-grayish discoloration of the target tissue at the end of the procedure is recommended.<sup>7</sup> As published by Journée-de Korver,<sup>2</sup> thermotherapy is different from hyperthermia, which by definition is heating the tumor to a temperature of 42–44°C to enhance the cytotoxic effect of ionizing radiation on tumor cells. In TTT temperatures of approximately 45–60°C within the tumor are reached with irreversible cytotoxic effects so that additional radiotherapy may be not required.<sup>7</sup>

Infrared or near-infrared light penetrates deeper into the choroidal tissue than light from argon blue–green lasers, theoretically avoiding undesirable coagulation effects in the retina. In contrast to other wavelengths, the absorption of ocular media for infrared is very low (approximately 4–7%). Disadvantages include the invisibility of the actual laser beam resulting in the need of an aiming beam and an increased risk of choroidal hemorrhage because of the deeper penetration of the laser light. Numerous light sources based on a semiconductor diode lasers are commercially available which may be used for TTT.

In clinical practice TTT is performed in retrobulbar anesthesia using a slit lamp and a contact lens. A laser beam with a spot size of 3 mm and a maximal power density of 12 W/cm<sup>2</sup> is used. At the second half of the exposure time of at least one minute a grayish discoloration of the tumor tissue should be visible, indicating a temperature of the target tissue of 60–65°C. Ideally no occlusion of retinal vessels and no coagulation effects in the overlying retina should occur. Three to four treatment sessions are needed, which should result in an atrophic scar with central pigment and visible sclera at the treatment site. TTT is limited to tumors not exceeding 3.5 mm thickness and 10 mm in largest tumor diameter.<sup>8</sup>

Potential complications of TTT include accidental combustions of the anterior segment and posterior segment complications including macular pucker, branch retinal vein occlusion, macular edema, vitreous and/or retinal hemorrhage, branch retinal artery occlusion,

retinal detachment, and retinal neovascularization. At least one of these complications may occur in 78% of patients.<sup>9</sup> Vitreomacular traction as a consequence of posterior hyaloid traction may be caused by TTT necessitating vitreoretinal surgery.<sup>10</sup>

Experimental data provided evidence that the absorption of heat is enhanced in particular in amelanotic tumors by systemic administration of a chromophore such as indocyanine green immediately before TTT.<sup>11</sup> Although a prospective randomized trial did not find any beneficial effect in supplemental use of indocyanine green in TTT of choroidal melanomas,<sup>12</sup> other authors did find enhanced local tumor control when indocyanine was used in combination with TTT.<sup>13</sup>

## TTT as Primary Treatment of Choroidal Melanoma

When TTT was introduced in the treatment of choroidal melanoma, short-term follow-up data suggested that tumor regression may be achieved in more than 90% in appropriate cases. Tumors considered as being appropriate for TTT included melanomas with a largest tumor diameter of less than 12 mm and not more than 4 mm thickness located posterior to the equator where the clinical diagnosis of a malignant melanoma was established.<sup>14</sup>

However, the initial enthusiasm was dampened after reports showing that conventional photocoagulation and TTT may be not as different as previously thought.<sup>15</sup> Juxtapapillary tumors, in particular when the tumor was abutting or overhanging the optic disc, and tumors requiring more than three sessions for tumor control were more likely to develop tumor recurrence<sup>16-24</sup> (Fig. 152.1). Histopathologic evaluation in a series of seven eyes enucleated after TTT detected lateral growth of the tumor and an extrascleral extension in 5 out of 7 cases, which were detected only in a single case ultrasonographically.<sup>25</sup> Other groups also reported extrascleral extension after TTT.<sup>25-27</sup> Progressive choroidal vascular remodeling and retinochoroidal anastomosis in sequential indocyanine green angiograms may indicate recurrent tumor growth after TTT, indicating that vascular occlusion after TTT is not complete.<sup>28,29</sup>

**FIG. 152.1** Marginal recurrence of choroidal melanoma at the posterior pole 18 months after transpupillary thermotherapy (TTT).

These controversial aspects of TTT as sole treatment of choroidal melanomas have been reviewed by a group of ocular oncologists.<sup>15</sup> They found recurrence rates as high as 56%.<sup>19</sup> In addition, in a recent study Shields and coworkers analyzed 391 cases with primary TTT for choroidal melanoma. In patients treated from 1995 to 2000, Kaplan–Meier estimates showed a recurrence rate of 42% after 10 years. Patients treated from 2001 to 2012 had a lower recurrence rate of 15% at 10 years but had thinner tumors (2.2 mm vs. 2.7 mm), where more distant from the optic disc and the macula compared to the 1995–2000 series. The authors identified risk factors for recurrence including occurrence of symptoms, closer location to the optic disc and the presence of subretinal fluid, treatment of recurrences after TTT with TTT, and a higher risk of extraocular tumor extension. Visual acuity decreased in 44% of all patients after completion of treatment.

## TTT as Ancillary Treatment of Choroidal

## Melanoma

Mainly because of the high recurrence rate, with its potential impact on metastasis sole treatment of choroidal melanomas should only be performed in eyes with no other treatment options (e.g., elderly patients).<sup>30</sup> However, TTT as ancillary treatment offers promising options.<sup>9,31</sup>

TTT may be applied prior or during treatment or after completing brachytherapy. The simultaneous use of TTT and (local) brachytherapy of uveal melanomas has been originally suggested by the Leiden Group as “sandwich therapy” (brachytherapy of the tumor base and TTT of the tumor apex) as both treatment modalities may be synergistic. The rationale for “sandwich therapy” is the enhanced cytotoxic effect of radiation and the potential reduction of radiation dose when thermotherapy and radiation are combined.<sup>32</sup>

Since its introduction several authors have evaluated “sandwich therapy” of choroidal melanomas. Early reports published significant advantages in terms of local tumor control and preservation of visual function.<sup>33–35</sup> More recent studies, however, could only detect slight advantages of “sandwich therapy” over brachytherapy, if any,<sup>36,37</sup> or even worse results in terms of deteriorated visual function in the “sandwich therapy” group.<sup>38</sup>

As sole TTT and simultaneous TTT and brachytherapy have not proven to be advantageous over brachytherapy alone, TT as ancillary treatment in selected cases of choroidal melanoma after brachytherapy is in the focus of interest. Several recent studies have shown that this approach offers distinct advantages in selected cases of choroidal melanoma. In particular in tumors overhanging or encircling the optic disc, more eyes can be preserved in the group of patients with combined treatment.<sup>39</sup> A better visual outcome could not be achieved.<sup>36</sup> The planned use of TTT, however, appears to protect against neovascular glaucoma and secondary enucleation in the first 5 years after treatment<sup>40</sup> (Figs. 152.2 and 152.3).

**FIG. 152.2** (A) Juxtapapillary choroidal melanoma with insufficient radiation scar at the central edge of the tumor after beta ray brachytherapy. (B) Immediately after ancillary transpupillary thermotherapy (TTT) of the tumor remnants. (C) 3 months after ancillary TTT with chorioretinal scar at the central edge of the tumor but vascular occlusion and retinal hemorrhages peripheral to the tumor.

**FIG. 152.3** (A) Choroidal melanoma underlying the temporal superior vessel arcade. (B) 4 months after beta ray brachytherapy with insufficient tumor regression at the central tumor margin. (C)  $3\frac{1}{2}$  years after brachytherapy and supplemental transpupillary thermotherapy (TTT).

Geographic misses may complicate radiotherapy of posterior choroidal melanomas due to inappropriate positioning of the plaque or plaque tilt. Detection of plaque tilt by ultrasonography allows supplemental TTT after brachytherapy, reducing the rate of recurrences to 3.6%.<sup>31</sup> Geographic misses may be unavoidable when the tumor is overhanging or partially surrounding the optic disc margin. In these cases supplemental TTT may improve the rate of eye preservation,<sup>41</sup> although the potential benefit is discussed controversially.<sup>36,39,42</sup> Additionally, TTT may be used after transscleral or transretinal surgical excision to prevent recurrent tumor growth at the edges of the pseudocoloboma. Interestingly,

monosomy 3, which is a highly significant marker for metastasis in choroidal melanoma, is correlated with faster tumor regression after combined brachytherapy and TTT.<sup>43</sup>

TTT as ancillary treatment was evaluated in radiotherapy modalities other than brachytherapy, such as proton radiation.<sup>44</sup> In this series, large uveal melanomas between 7 and 15 mm thickness were randomized for proton treatment alone and for combined treatment with three sessions of TTT after radiation with a significant lower secondary enucleation rate and less exudative retinal detachment in the latter group.

## **Laser Photocoagulation as Ancillary Treatment for Uveal Melanoma**

### **Radiation Retinopathy, Radiation-Induced Optic Neuropathy**

Radiation techniques are well established in eye salvaging treatment of uveal melanoma but may be complicated by radiation-related complications like radiation retinopathy and radiation optic neuropathy. Incidence and severity of these complications are related to the radiation dose used, the dose distribution of the radiation source (beta ray plaques, gamma ray plaques or external beam sources like proton beam), and the location of the tumor (posterior or anterior to the equator). Radiation retinopathy is a slowly progressive, delayed-onset disease of retinal blood vessels due to changes in the structure and permeability of the retinal vessels.<sup>45</sup> Characteristic clinical findings are macular edema, capillary nonperfusion, cotton-wool spots, capillary telangiectasia, retinal neovascularization, microaneurysms, retinal hemorrhages, intraretinal exudation, and neuronal changes such as disc edema, disc pallor, optic nerve atrophy, and neovascularization of the disc.<sup>46,47</sup>

If proliferative retinopathy remains untreated, rubeosis of the iris and secondary neovascular glaucoma may occur. There is no effective treatment to cure vision loss due to radiation retinopathy. Panretinal photocoagulation, however, is effective in preventing

complications related to radiation-induced ocular ischemia.<sup>46,48</sup> Macular edema is a frequent complication of radiotherapy of uveal melanomas, in particular if macular edema is present prior to radiotherapy. Radiation-induced macular edema may benefit from focal laser treatment.<sup>49</sup> New options include intravitreal VEGF inhibitors in analogy to the treatment of diabetic macular edema or the combination of both treatment options.<sup>48</sup> Macular edema may be prevented by early sector photocoagulation after brachytherapy.<sup>50,51</sup>

## Resection of Uveal Melanoma

The benefit of photocoagulation prior to surgical excision of an uveal melanoma is still unclear and subject of a controversial discussion. TTT or conventional photocoagulation is effective in reducing the risk of continuous or recurrent tumor growth after surgical excision. Damato and colleagues have recommended the use of photocoagulation at the edges of the pseudocoloboma as part of the routine management of patients following transscleral local resection.<sup>52</sup> In endoresection endolaser coagulation of the tumor site, particularly of the tumor edges, is mandatory because of the high risk of incomplete removal of tumor tissue.

## Exudative Retinal Detachment

Choroidal melanomas are frequently associated with exudative retinal detachment due to tumor-related vascular leakage. Moreover, extensive exudative retinal detachment is a well-known complication of brachytherapy of uveal melanoma and may lead to loss of vision and eventually enucleation.<sup>53</sup> Several authors have reported that scatter photocoagulation on the surface of the tumor may be effective in the management of melanoma-associated retinal detachment, which may be combined with vitreoretinal surgery, drainage of subretinal fluid, and fluid–air exchange. In charged particle therapy of uveal melanomas the ancillary use of laser thermotherapy significantly reduced the incidence and duration of exudative retinal detachment after radiation treatment.<sup>54</sup> Subthreshold transpupillary thermotherapy may be effective in the management of subfoveal fluid on small choroidal melanomas.<sup>55</sup>

# Photodynamic Therapy of Uveal Melanomas

The effect of photodynamic therapy (PDT) (photoradiation) is based on the cytotoxic effect of singlet oxygen radicals by photosensitizers when exposed to visible light. The first generation of photosensitizers used were hematoporphyrin derivatives (HpD).<sup>56</sup> HpD-based photodynamic therapy, however, had numerous disadvantages, including a high rate of recurrences (probably related to the poor tissue penetration of 630 nm laser light into tumor tissue), secondary glaucoma, and severe systemic side-effects.<sup>57</sup>

Benzoporphyrin-derived photosensitizers like Verteporfin developed for the treatment of choroidal neovascular membranes in age-related macular degeneration have been evaluated experimentally and clinically in the treatment of choroidal melanomas.<sup>58</sup> Verteporfin offers numerous advantages including better tissue penetration and fewer systemic side-effects with regard to skin toxicity and has been proven to be effective in the treatment of choroidal hemangioma.<sup>59,60</sup> Data from a series of patients with Verteporfin PDT prior to intentional enucleation demonstrated that PDT with Verteporfin is basically capable of destroying a choroidal melanoma using a light dose of 100 J/cm<sup>2</sup>. In this series tumor necrosis was induced in a depth up to 2.5 mm using a light dose  $\geq 100$  J/cm<sup>2</sup> demonstrating the potential of PDT with Verteporfin to induce tumor necrosis.<sup>61</sup> To date six reports with 38 patients having Verteporfin PDT as first-line treatment of a choroidal melanoma have been reported.<sup>62</sup> In eight patients tumor recurrence occurred. Tumor pigmentation prevents tissue penetration of the laser with a lack of tumor destruction,<sup>63</sup> suggesting that PDT with Verteporfin is inadequate in most clinical cases of choroidal melanomas.

## Experimental Techniques

Photoablation of ocular melanoma has been reported so far in an animal model only.<sup>64</sup> The technique uses an intraocular 15-W argon

blue–green laser with a vitreous cutter used simultaneously to remove liberated tumor debris. A Dutch group presented experimental results in an animal model after transscleral laser thermotherapy of choroidal melanoma using an infrared diode laser, which was able to destroy the tumor and preserve the stability of the sclera.<sup>65</sup> To date no clinical results have been published. New laser sources introduced in treatment of experimental intraocular melanoma included a focused, raster-scanned beam from an Nd:ytrium–lanthanum–fluoride laser (1047 nm).<sup>66</sup>

## Introduction

In developed countries, patients with metastatic uveal melanoma rarely present with the classic “distended abdomen and artificial eye.” This change reflects a shift towards improved systemic surveillance after local treatment.<sup>1</sup> When metastasis is discovered using (every 6-month) radiographic abdominal imaging, most are asymptomatic. That said, early detection allows for both palliative treatment and enrollment in clinical trials, as well as more time to plan future medical and personal care.

Survival extends from 2.5 months to 14 months in patients with the lowest tumor burden at diagnosis. Eskelin and associates found that the largest tumor dimension of metastasis could be correlated to median patient survival.<sup>2-4</sup> Thus, periodic screening aims to uncover smaller, less numerous even solitary metastases where treatment has the opportunity to prolong or improve lives of patients with metastatic uveal melanoma.

The liver is the most commonly involved organ.<sup>4</sup> Therefore periodic radiographic abdominal imaging is currently the most widely recommended method for early detection of metastases. Though the liver is involved in over 90% of cases, common alternative sites include bone and subcutaneous skin. There are few published practice guidelines for staging and screening of metastatic uveal melanoma.<sup>1,5</sup>

## Physical Examination

Retinologists and eye cancer specialists will not disrobe patients for examination. However, they can still play an integral “surveillance” role during their periodic patient interactions. For example, a history of weight loss, subcutaneous nodularity or abdominal pain should raise suspicion of metastatic uveal melanoma. The specialist should ensure coordinated systemic patient care, including periodic

physical examinations and clinical testing. The retinal specialist should use the recently validated American Joint Committee on Cancer (AJCC) uveal melanoma staging system to determine metastatic risk<sup>3,6,7</sup> (Fig. 153.1).

No. at Risk						
I:	1030	741	446	270	118	49
IIA:	1095	766	431	251	126	52
IIB:	710	460	272	166	83	31
IIIA:	282	156	88	43	18	6
IIIB:	79	40	15	6	2	1
IIIC:	21	13	4	2	-	-

**FIG. 153.1** AJCC Validation Study: Kaplan–Meier curves of metastasis based on T-stage.<sup>6</sup> (Reproduced with permission from International Validation of the American Joint Committee on Cancer's 7th Edition Classification of Uveal Melanoma. AJCC Ophthalmic Oncology Task Force. JAMA Ophthalmol 2015;133(4):376-83.)

Uveal melanoma patients benefit from co-management with a medical oncologist. Referral allows for a relationship to be built prior to metastatic disease, as well as participating in diagnostic and treatment-focused clinical trials.

## Serology: Liver Function Tests

Liver function tests (LFTs) include gamma-glutamyl

transpeptidase, lactate dehydrogenase, alkaline phosphatases, aminotransferases, and bilirubin.<sup>8</sup> When considered individually, LFTs have demonstrated reported sensitivities ranging between 0.27 and 0.67 for metastases detection.<sup>8</sup> However, from the 2320 patients enrolled in the Collaborative Ocular Melanoma Study (COMS), they concluded that sensitivity, specificity, positive predictive value, and negative predictive value associated with at least one abnormal LFT before diagnosis of metastatic disease were 14.7%, 92.3%, 45.7%, and 71.0%, respectively.<sup>8</sup> Therefore, LFT screening is less sensitive and less specific for diagnosis of hepatic metastases compared to periodic radiographic imaging.

## Radiologic Screening for Liver Metastasis

The liver is easily visualized by radiographic imaging. Computed tomography (CT), magnetic resonance imaging (MRI), and ultrasonography (US) are widely available. It is commonly accepted that US is better than LFTs for uncovering metastases.<sup>9</sup> Triphasic CT has shown excellent sensitivity, but has a low positive predictive value due to imaging of benign lesions.<sup>10</sup> Contrast-enhanced (gadoxetate disodium, gadolinium) MRI is the most sensitive hepatic imaging tool<sup>11,12</sup> (Fig. 153.2, top). However, there exists concern about gadolinium-associated renal toxicity, and it is contraindicated for patients with metallic implants.<sup>13</sup> Typically, the choice of imaging is largely governed by preference, cost, and radiation exposure.

**FIG. 153.2** (Top) Contrast-enhanced, T2-weighted magnetic resonance imaging reveals a solitary metastasis (*arrow*) from a primary uveal melanoma. Bottom, a series of images that demonstrate computed tomography (CT) alone demonstrating anatomy (right), 18-fluorodeoxyglucose positron emission tomography (PET) demonstrating physiologic glucose uptake (center), and PET/CT allowing for an evaluation of CT-form and PET-function in the same image. Note the metastatic focus (*arrow*).

## Positron Emission Tomography/Computed Tomography (PET/CT)

PET/CT was the first to combine PET-function to CT-form on the same diagnostic page ([Fig. 153.2, bottom](#)). Unlike the previously mentioned radiographic imaging modalities, anatomophysiological imaging improved discrimination between inflammatory, infectious, and neoplastic tumors.<sup>4,14,15</sup> Unlike abdominal CT, MRI,

or US, PET/CT allows for scanning of the entire body and thus systemic staging and restaging. Freton and others have found whole body PET/CT yields remarkably high positive predictive value for detection of metastatic uveal melanoma.<sup>4</sup>

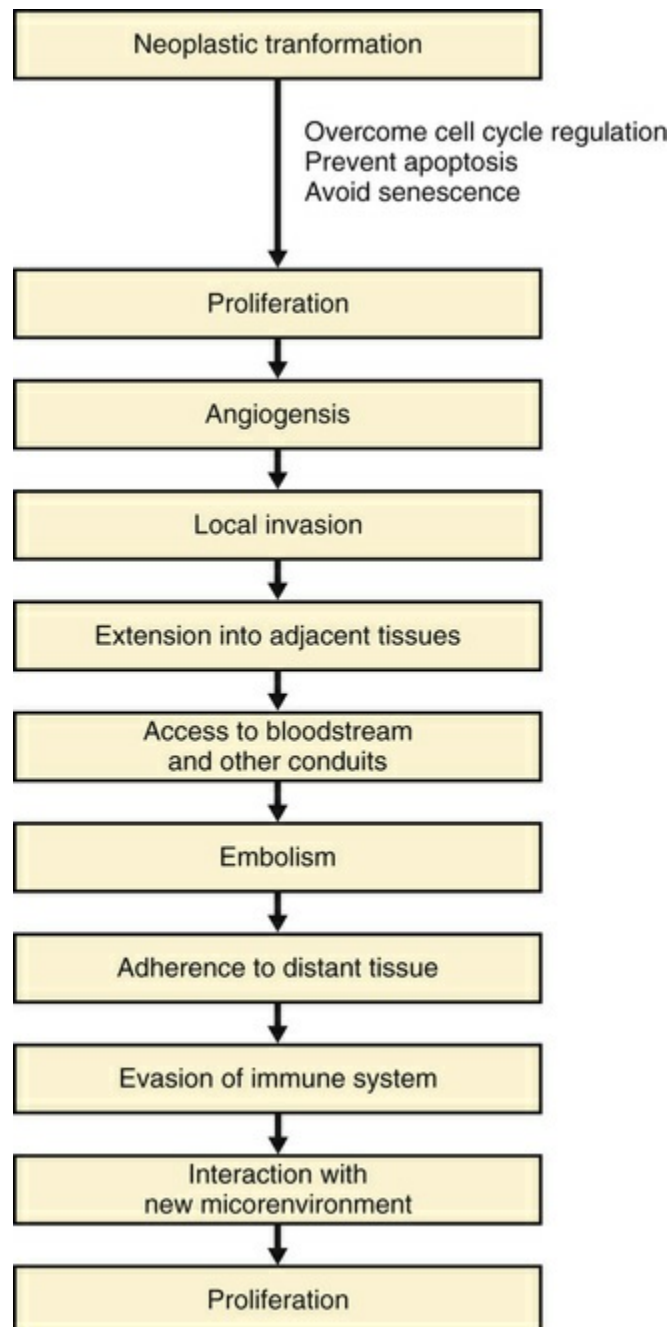

PET/CT has also been used to detect synchronous nonocular cancers, as a biomarker to determine risk for metastatic uveal melanoma, for evaluation of postirradiation tumor viability, and for clarification of suspicious CT or MRI findings.<sup>4,16-18</sup> These benefits of PET/CT screening have been downplayed due to radiation risks and monetary cost. However, patients at high risk for metastatic uveal melanoma – AJCC-T3, AJCC-T4 tumors, tumors with extrascleral extension, ciliary body extension, and those who locally recur – are the subgroups most likely to benefit from initial PET/CT staging and subsequent PET/CT surveillance.<sup>4</sup>

## Pathology, Genetics, and Molecular Biology

Histopathologic features of primary uveal melanoma (cellular subtype, extracellular vascular matrix patterns, and mitotic index) have been studied as biomarkers for metastatic risk.<sup>1</sup> Further, cytogenetic changes within tumors (e.g., loss of a chromosome 3, gene expression profiling) appear to be relevant genetic risk factors affecting metastatic spread.<sup>19-21</sup> Moreover, gain of chromosome 8q increases the risk of spreading, whereas gain of chromosome 6p seems protective.<sup>1</sup> Recently, genetic mutations have been identified within primary ocular melanomas, which may offer potential therapeutic targets for treatment.

First, mutations in GNAQ/GNA11 are early events in tumorigenesis and may or may not be prognostic for tumor stage or metastatic spread.<sup>22</sup> In contrast, mutations in the BRCA1-associated protein-1, BAP1, have been strongly linked to metastatic spread and poor patient survival.<sup>20</sup> Inactivation of BAP1 most often occurs through mutation of one allele and subsequent loss of an entire copy of chromosome-3 (monosomy 3) to unmask the mutant copy.<sup>23</sup> Research is examining clinical, histopathologic, cytogenetic, and biomarker expression profiles is being conducted to understand

how melanoma cells gain the ability to metastasize during tumor development. Clearly, the physiologic process called metastasis is complex (Fig. 153.3).

**FIG. 153.3** Though melanoma cells develop from mutational genetic events, that is just the beginning. Cancer cells must then overcome cellular safeguards against neoplastic transformation. If successful, the tumor typically encounters limited space, lack of nutrients and oxygen, that select further genetic

mutations allowing the tumor to recruit a blood supply, invade other tissues, and spread to distant sites (to set up new tumor colonies). Certainly, the process called “metastasis” is dependent upon many factors. (Reproduced from Survey of Ophthalmology, volume 47, number 1, Jan–Feb 2002, pp. 1-16.)

## Ethical Considerations of Screening and Biopsy

Patients who agree to a metastatic workup should benefit from a more favorable outcome. While LFTs and abdominal ultrasonography are relatively noninvasive, CT, MRI, and PET/CT carry the aforementioned collateral health risks.

Intraocular biopsy has recently gained popularity along with the evolution of genetic tumor analysis. Here, the low risks of intraocular biopsy (hemorrhage, infection, retinal detachment, tumor dissemination) must be balanced against the value of a histopathologic diagnosis and information about metastatic potential. The latter being used to select higher-risk patients for heightened surveillance and clinical trials.

In addition, histopathology and genetic tumor analysis can also be obtained from metastatic tumors. Though this approach does not allow prior selection for treatment of presumed subclinical disease, it does permit directed therapy.

## Treatment of Metastatic Disease

### Liver Metastases

The liver is the most common initial site of metastatic spread.<sup>1</sup> However, most patients are found to have multifocal hepatic or multiorgan metastasis untreatable by surgical metastasectomy.<sup>4,9,11</sup> Patients who metastasize more than 5 years after initial treatment with a solitary liver lesion have the longest disease-free interval.<sup>24</sup> Local control or palliation of liver metastases can be achieved with a wide range of procedures (hepatic artery chemoembolization, hepatic perfusion, or radiofrequency ablation).<sup>25</sup> Procedure

selection is made in consideration of the extent of hepatic disease, the location of the tumors, the patient's performance status, and the institution's interventional capability. Multifocal liver metastases not amenable to local therapy and those with multiorgan disease should be treated within clinical research studies.

## Systemic Metastases

The gold standard for the treatment of diffuse metastatic disease from uveal melanoma is enrollment into a clinical trial.<sup>26</sup>

Unfortunately, conventional chemotherapy and immunotherapy has failed to demonstrate significant efficacy. Recently, new insights regarding biomarkers, genetic targets expressed by tumor cells, as well as antiangiogenic agents, are leading innovative treatment strategies. Nevertheless, for patients with multiorgan metastases, there is still no known treatment intervention that offers cure.

In time, a combination of genetic tumor typing, improved understanding of the pathophysiology of metastasis, and the host's immune capabilities will enable physicians to define high- and low-risk patients. High-risk patients will be offered a primary treatment and an adjuvant clinical trial (for presumed subclinical metastatic disease).<sup>2,6,19,27</sup> Low-risk patients will continue to require treatment and (perhaps less intensive) systemic surveillance. Adjuvant therapy trials will concentrate on the genetic, molecular, and physiologic targets. Current programs have targeted methods to enhance the patient's immune system and blocking tumor dissemination. These strategies are aimed at making metastatic uveal melanoma a much more manageable, preventable or chronic illness.

## Introduction

A large number of excellent clinical studies concerning treatment of ocular melanoma have been cited elsewhere in this text. The Collaborative Ocular Melanoma Study (COMS) was the first set of randomized clinical trials designed and conducted with sufficient power to compare survival outcomes between two or more treatments for this primary ocular cancer with a high degree of confidence.

## Background

The choice of management of choroidal melanoma was controversial in the early 1980s when the COMS was designed and initiated; it remains controversial for tumors of small size. No data comparing enucleation or any other treatment with natural history were available; however, most ophthalmologists and oncologists were unwilling to undertake a randomized trial in which observation was one of the treatment arms. Large choroidal melanoma in the absence of metastasis traditionally has been treated with enucleation of the affected eye. Pre-enucleation irradiation of the eye had been proposed with the goal of minimizing the possibility of dissemination of viable tumor cells at time of enucleation.<sup>1-8</sup> Other adjunctive treatments also had been proposed, including post-enucleation irradiation of the socket, cryotherapy before enucleation, and chemotherapy.

There was consensus that growing choroidal melanoma of

intermediate size (“medium”) should be treated. However, the choice of treatment, enucleation or some type of radiotherapy to avoid loss of the eye and preserve some vision, was unclear. At the time the COMS was designed, radiotherapy was available at relatively few centers within the United States and Canada, where patients who elected radiotherapy were referred. Concerns regarding diagnostic accuracy, particularly for small choroidal melanoma, persuaded most ophthalmologists to observe smaller tumors for growth before treating.

The length of survival after a diagnosis of choroidal melanoma is quite variable. A meta-analysis of data published from 1966 through 1988 regarding survival following enucleation yielded 5-year survival rates of 50% for large choroidal melanoma, 70% for medium choroidal melanoma, and 85% for small choroidal melanoma,<sup>9</sup> but few studies had reported survival or mortality rates by tumor size. It is accepted that the most important predictor of survival is tumor cell type. However, because of concerns regarding complications and inadequate sampling during fine-needle aspiration biopsy, choroidal melanoma may not be biopsied. Thus, cell type is not known until the eye is removed or the patient dies. Also, the cell type(s) may change over time.

## **Design of the Collaborative Ocular Melanoma Study (COMS)**

The COMS was designed as a set of clinical trials of treatment for choroidal melanoma to be conducted by a group of investigators in the United States and Canada. Events leading to the design and initiation of the COMS have been summarized elsewhere.<sup>10</sup> Initially, three separate studies were undertaken, two randomized clinical trials and one observational study.<sup>11</sup> Initial funding was provided in 1985 through cooperative agreements with the National Eye Institute, National Institutes of Health, US Department of Health and Human Services; beginning in 1991, the National Cancer Institute also provided funding to conduct the study.

## **Randomized Trials of Radiotherapy**

For COMS purposes, choroidal melanoma was categorized broadly by size. Size criteria are summarized in [Table 154.1](#); other eligibility criteria are provided elsewhere<sup>12</sup> and have been published.<sup>13,14</sup>

**TABLE 154.1**

**Collaborative Ocular Melanoma Study Classification of Size of Choroidal Melanoma**

Size	Parameter		
	Apical Height (mm)	Longest Tumor Basal Diameter (mm)	Distance to Optic Disc (mm)
<b>NOVEMBER 1986 THROUGH NOVEMBER 1990</b>			
<b>Large</b>

<b>Small</b>			
Subgroup 1	<2.5	<16	—
Subgroup 2	<2	>16	—

—, No restriction.

The COMS randomized clinical trial of primary interest was designed to compare survival of patients following enucleation alone with iodine-125 (I-125) brachytherapy for treatment of “medium” choroidal melanoma who were believed to comprise the majority of newly diagnosed cases. Brachytherapy was chosen as the most feasible method of radiation delivery to the melanoma with respect to standardization of dosimetry and ability to monitor adherence to the radiotherapy protocol. Iodine-125 was selected as

the isotope because of the ability to protect the surgeon and other tissues in the orbit from radiation damage by using a gold shield and because of the half-life of the isotope.<sup>15</sup> Eligible consenting patients were assigned randomly with equal probability between enucleation and I-125 brachytherapy. All patients were to be followed for a minimum of 5 years or until death. The minimum sample size targeted a priori was 1250 patients for comparison of overall survival between treatment arms based on conventional Type I and Type II errors of 0.05 and 0.20, respectively. A desired sample size of 2400 patients also was established a priori to provide more precise estimates of survival overall and within patient subgroups and for evaluation of secondary outcomes.<sup>11,12</sup> The desired sample size was based on Type I and Type II errors of 0.01 and 0.10, respectively.

The clinical trial for “large” (high-risk of metastasis and death) choroidal melanoma was designed to compare enucleation alone with pre-enucleation radiation treatment (PERT). Pre-enucleation radiation was chosen for comparison with enucleation alone because a similar approach had been shown to be effective in other types and sites of cancer in which surgery was employed. In addition, external radiation was widely available throughout the United States and Canada. Patients were assigned randomly, with equal probability, between the two treatment arms and were to be followed for a minimum of 5 years or until death. The sample size was estimated on the basis of overall survival. Taking account of possible losses to follow-up, treatment crossovers, and treatment refusals, a target sample size of 1000 patients was established a priori based on Type I and Type II errors of 0.01 and 0.10, respectively.<sup>11-13</sup>

A parallel study of quality of life of patients enrolled in the randomized trial of I-125 brachytherapy for medium choroidal melanoma was initiated in 1994.<sup>16</sup> The purpose of the parallel study was to compare treatment arms over time with respect to general health, vision-related function, anxiety, and depression using scores from several standard interview instruments. The study had two components: (1) a prospective randomized component consisting of 209 participants in the trial of I-125 brachytherapy who were interviewed prior to random treatment assignment, at 6 months

following treatment, and on annual anniversaries of enrollment for up to 8 years; and (2) a cross-sectional component consisting of 645 additional patients who had enrolled in the randomized trial before the quality of life study was initiated and who were interviewed at least once during scheduled follow-up. These 854 patients represent 90% of patients who were eligible for the quality of life study and 65% of all patients who enrolled in the trial of I-125 brachytherapy.

## Observational Study

A nonrandomized observational study of small choroidal melanoma was included in the initial COMS design with the goal of providing sufficient information to design a randomized clinical trial of treatment for small tumors. Primary objectives were to estimate the number of patients with small choroidal melanoma available for inclusion in a randomized trial, the methods of treating small choroidal melanoma most widely used by COMS investigators, and, to the extent feasible within a small pilot study with short patient follow-up, rates of tumor growth and patient death.

## Methods

The COMS design and many of the methods have been published; the COMS Manual of Procedures<sup>12</sup> is available. Patients were evaluated for eligibility, enrolled, and treated at 43 different clinical centers, 41 in the United States and two in Canada. A standard schedule of clinical examinations was followed for data collection purposes. An unusual feature of the COMS design was that the participating ophthalmologists reported de-identified basic demographic information (age, gender, race, or ethnicity) and tumor dimensions for all cases of choroidal melanoma examined during the period of patient accrual, regardless of tumor size, eligibility for the COMS, or willingness of eligible patients to enroll in the COMS.

Responsibility for random assignment to treatment, oversight of data collection, data management, and data analysis was assigned to the COMS Coordinating Center in Baltimore, Maryland. This

center also had major responsibility for monitoring the quality of data provided by the participating centers. Other resource centers with major quality assurance and monitoring responsibilities included an Echography Center (Miami, Florida; later Mars Hill, North Carolina), where tumor height was measured independently from photoechograms; a Photograph Reading Center (Iowa City), where tumor characteristics at baseline and postirradiation changes in the posterior retina during follow-up were assessed and recorded; a Pathology Center (Boston, Massachusetts; later Madison, Wisconsin), where tumor size and diagnosis were confirmed from all eyes enucleated; and the Radiological Physics Center (Houston, Texas), where adherence to the radiotherapy protocols was monitored. Overall leadership responsibility for the COMS Group was vested in the COMS Chairman's Office (Baltimore, Maryland; later Philadelphia, Pennsylvania).

An independent Data and Safety Monitoring Committee, appointed by the Director of the National Eye Institute, was the only group with access to survival data from the randomized clinical trials by treatment arm until this committee judged that the objectives of each individual trial had been met. This group had responsibility for ensuring that COMS trials were conducted in a scientifically valid and ethically sound manner. Scientific leadership of the COMS was provided by the Executive Committee, whose members included representatives of both the resource centers and the participating clinical centers. Three ophthalmic pathologists comprised the Pathology Review Committee who reviewed every enucleated eye from COMS patients to determine whether the clinical diagnosis of choroidal melanoma was correct. Mechanisms for quality assurance and monitoring were developed by the Quality Assurance Committee, which oversaw all aspects of data collection and protocol adherence. Classification of causes of death was the responsibility of the Mortality Coding Committee, whose members did not have responsibility for medical care of COMS patients. Since completion of the COMS, the COMS Archives Committee has had responsibility for reviewing and approving applications for access by researchers to original COMS data and for reviewing manuscripts that use COMS data.

## Chronology of the COMS

Accrual of patients to the randomized trial of pre-enucleation radiation (PERT) of large choroidal melanoma began in November 1986 and ended in December 1994, with 1003 patients enrolled. Scheduled clinical follow-up of all surviving patients for vital status, incidence of metastasis and second cancers, and complications continued until July 31, 2000. Interim mortality findings and related information that emphasized 5-year outcomes were published in 1998;<sup>13,17,18</sup> mortality findings through 10 years and prognostic factors were published in 2004.<sup>19</sup>

Accrual of patients to the randomized trial of I-125 brachytherapy for medium choroidal melanoma began in January 1987 and ended in July 1998, with 1317 patients enrolled, at the recommendation of the Data and Safety Monitoring Committee. Scheduled clinical follow-up of all surviving patients, for clinical and vital status and for quality of life, continued until July 31, 2003, and October 31, 2003, respectively. Interim mortality findings were published in 2001;<sup>14</sup> mortality findings through 12 years after enrollment and subgroup findings were published in 2006.<sup>20</sup> Information about complications<sup>21-23</sup> and related information<sup>24</sup> also has been published.

Patient accrual to the nonrandomized study for small choroidal melanoma began in 1987 and ended in 1989, with 204 patients enrolled. Annual follow-up examinations were halted in 1991 as a result of funding constraints. Vital status and treatment status were reassessed in 1993 through 1994, and again in 1995 through 1996, for all patients who had not been lost to follow-up. Findings from this study have been published.<sup>25,26</sup>

The COMS database, copies of all publications from the COMS Group, and the *COMS Manual of Procedures* were deposited in the Alan Mason Chesney Medical Archives at the Johns Hopkins University in August 2008. An anonymized public use dataset, containing baseline characteristics and survival outcomes, the *COMS Manual*, and copies of all COMS publications are available by application to the Medical Archives (<http://www.medicalarchives.jhmi.edu>). Access to more extensive data, including images of original data forms received at the COMS Coordinating Center, is available to qualified researchers whose

application to the COMS Archives Committee (via: [schacha@ccf.org](mailto:schacha@ccf.org) or [bhawkins@jhmi.edu](mailto:bhawkins@jhmi.edu)) is approved by the COMS Archives Committee and by the Medical Archives institutional review board.

## **Findings From the COMS Trial of I-125 Brachytherapy for Medium Choroidal Melanoma**

### **Participants**

By July 1998, a total of 8712 patients with choroidal melanoma had been reported by COMS investigators; 5046 were classified to be of medium size by COMS criteria (Table 153.1). Among 2882 patients eligible for the randomized trial of I-125 brachytherapy versus standard enucleation, 1317 patients gave signed consent, enrolled, and were assigned randomly to treatment arm: 660 to standard enucleation and 657 to I-125 brachytherapy. Treatment arms were well balanced; adherence to the COMS protocol was excellent.<sup>14</sup> All but 21 patients, seven in the brachytherapy arm and 14 in the enucleation arm, were treated promptly as assigned. Three patients assigned to brachytherapy crossed over to enucleation, seven enucleation patients crossed over to brachytherapy, and two had proton beam radiation as the initial treatment. At the end of clinical follow-up in 2003, the vital status 5 years after enrollment was known for 1313 patients (99.7%), i.e., for all but four patients in the enucleation arm. Of 799 patients eligible for 10 years of follow-up, the vital status at 10 years was known for 791 (99.0%), i.e., for all but one patient in the brachytherapy arm and seven patients in the enucleation arm.

### **Survival Estimates**

By September 30, 2000, all patients had been followed for vital status for 2 years or longer, with 1274 patients followed for 3 years or longer and 1072 patients eligible for 5 years of follow-up. Among patients in the enucleation arm, 188 (28%) were known to have died compared with 176 (27%) of those in the brachytherapy arm.

Estimated 5-year survival rates and 95% confidence intervals were 81% (95% CI 77–84%) in the enucleation arm and 82% (95% CI 79–85%) in the brachytherapy arm. Of the 364 decedents, 159 were judged to have had melanoma metastasis at time of death. Neither all-cause mortality rates nor rates of death with histopathologically confirmed melanoma metastasis differed between treatment arms. Adjustment of mortality rates for independent and statistically significant predictors of time to death (baseline age, tumor dimensions, tumor location, tumor shape, smoking history, and coexisting medical conditions) changed the estimated risk ratio from 0.93 (unadjusted; 95% CI 0.76–1.14) to 0.99 (adjusted; 95% CI 0.80–1.22).

Clinical follow-up of patients in the trial of I-125 brachytherapy ended on July 31, 2003, after all patients had been followed for at least 5 years up to a maximum of 15 years. Five-year survival rates were similar to those published in 2001, i.e., 81% in each treatment arm, yielding a pooled 95% CI of 79–83%. Ten-year survival rates also were the same in the two arms: 65% (95% CI 62–68%). Mortality rates by treatment arm for all causes and with melanoma metastasis are shown in [Fig. 154.1](#). Older age and maximum basal tumor diameter were the primary predictors of earlier death.<sup>20</sup> Pooled data were used to summarize mortality, diagnosis of melanoma metastasis,<sup>27</sup> and second primary cancers<sup>28</sup> through 12 years<sup>20</sup> ([Fig. 154.2](#)).

## Complications

As reported in 2002,<sup>21</sup> 69 of the 650 patients whose eyes were treated with brachytherapy had the eye enucleated during the first 5 years after initial treatment, yielding a 5-year rate of 12% (95% CI 10–16%); local treatment failure was reported for 57 eyes in the same time period, with a 5-year cumulative rate of 10% (95% CI 8–13%). Local treatment failure accounted for 39 of the 69 enucleations. The 3-year cumulative rate of loss of 6 or more lines of visual acuity from baseline was 49% (95% CI 44–53%), and the 3-year cumulative rate of loss of visual acuity to 20/200 or worse was 43% (95% CI 38–48%).<sup>22</sup> Five-year estimates of cataract among the 532 eyes treated with I-125 brachytherapy that were phakic at baseline and had no history of cataract in the eye were 83% (95% CI 79–87%).<sup>23</sup>

## Quality of Life

In the parallel study of quality of life, 206 of 209 patients who enrolled and were treated as assigned (103 each to enucleation or to I-125 brachytherapy) provided 5-year findings regarding quality of life.<sup>29</sup> Patients treated with brachytherapy reported significantly better peripheral vision and ability to drive than those treated with enucleation for up to 2 years following treatment. Differences between treatment arms diminished thereafter in parallel with declining visual acuity in brachytherapy-treated eyes. Patients treated with brachytherapy reported more symptoms of anxiety through 5 years than those treated with enucleation.<sup>29</sup>

# Findings From the COMS Trial of Pre-Enucleation Radiation for Large Choroidal Melanoma

## Participants

From November 1986 through December 1994, COMS investigators reported 6078 patients with choroidal melanoma. Of these, 1860 had tumors classified as large by COMS criteria (see [Table 154.1](#) for definitions used). Of those classified as large, 1302 were judged eligible for enrollment; 1003 gave signed consent, enrolled, and were assigned randomly to enucleation alone or to pre-enucleation radiation. The two treatment arms were well balanced with respect to most of the many characteristics of patients, eyes, and tumors considered.<sup>13</sup> Adherence to the COMS protocol was excellent, as was diagnostic accuracy.<sup>13,30</sup> Only nine patients – three assigned to standard enucleation and six assigned to pre-enucleation radiation – were not treated as assigned at time of enrollment. When clinical follow-up ended in 2000, vital status 5 years after enrollment was known for 998 patients (99.5%), i.e., all but three patients in the enucleation alone arm and two patients in the pre-enucleation radiation arm.

## Survival Estimates

By July 31, 1997, the vital status at 3 years after enrollment was available for all but 26 patients who had enrolled during the last few months of patient accrual. The 5-year vital status was known for 801 (80%) of all patients enrolled: 238 patients assigned to enucleation alone (47%) and 219 patients assigned to pre-enucleation radiation (44%) were known to have died. The estimated 5-year cumulative survival rates and 95% confidence intervals were 57% (95% CI 52–62%) for patients assigned to enucleation alone and 62% (95% CI 57–66%) for patients assigned to pre-enucleation radiation. Neither 5-year survival rates nor survival rates over the first 8 years after enrollment differed between treatment arms, to either a statistically or clinically significant degree.<sup>13</sup>

Mortality by treatment arm and by time since enrollment when clinical follow-up ended in July 2000 is summarized in [Fig. 154.3](#). Five-year survival rates were identical to those reported earlier; 10-year survival was similar in the two arms and yielded a pooled estimate of 39% (95% CI 35–42%).<sup>19</sup> Among baseline characteristics of the patients, eyes, and tumors evaluated for their potential as prognostic factors, only patient age at time of treatment and longest tumor basal diameter had statistically significant effects on the length of overall survival.<sup>19</sup>

**FIG. 154.3** (Top) The cumulative percentage of patients in the Collaborative Ocular Melanoma Study (COMS) trial of pre-enucleation radiation (PERT) for large choroidal melanoma who had died by specified times after enrollment. *Blue line*: patients assigned to PERT. *Red line*: patients assigned to enucleation alone. The numbers of patients at risk of death and

numbers censored, based on date of enrollment, are given at annual anniversaries of enrollment by treatment assignment. Event is death from any cause. (Bottom) The cumulative percentage of patients in the COMS randomized trial of PERT who had died with metastatic melanoma by the specified times since enrollment. *Blue line*: patients assigned to PERT. *Red line*: patients assigned to enucleation alone. The numbers of patients at risk of death and numbers censored, based on date of enrollment, are given at annual anniversaries of enrollment by random treatment assignment. Event is death with histologically confirmed metastatic melanoma. (Modified with permission from Collaborative Ocular Melanoma Study Group. Am J Ophthalmol 2004;138:936–57.)

Among patients assigned to enucleation alone, 130 (26%) died within 5 years of enrollment with histologically confirmed metastatic melanoma, compared with 139 (28%) patients assigned to pre-enucleation radiation, based on review of 435 of the 457 deaths by the Mortality Coding Committee.<sup>31,32</sup> Time to death with histologically confirmed metastatic melanoma is displayed in [Fig. 154.3](#). The liver was the most common site of melanoma metastasis.<sup>31</sup> Findings pooled by treatment arm for mortality, diagnosis of melanoma metastases, and second primary cancers are summarized through 10 years in [Fig. 154.4](#).

**FIG. 154.4** The percentage of patients in the Collaborative Ocular Melanoma Study (COMS) randomized trial of pre-enucleation radiation (PERT) with the specified status at the end of each year of follow-up, with treatment arms pooled. The number of patients who enrolled early enough to be followed up to the end of the specified year is shown at the top of the corresponding bar. (Reproduced with permission from Collaborative Ocular Melanoma Study Group. *Am J Ophthalmol* 2004;138:936–57.)

## Complications

Only 17 patients treated with enucleation alone and 19 patients treated with pre-enucleation radiation had any surgical or anesthetic complication reported at the time of initial treatment.<sup>18</sup> Orbital tumor recurrence was reported during the first 5 years of follow-up for six patients treated with enucleation alone and for one patient treated with pre-enucleation radiation; patients treated with enucleation alone had nearly twice the 5-year incidence of severe ptosis as reported for patients treated with pre-enucleation

radiation.<sup>18</sup>

## Findings From the COMS Nonrandomized Prospective Study of Small Choroidal Melanoma

Of 300 patients with small choroidal melanoma (by COMS initial criteria) reported from December 1986 through August 1989, 220 were judged eligible for this COMS observational substudy; 204 gave signed consent and enrolled. The majority of the patients enrolled within 1 year of the initial diagnosis of choroidal melanoma.<sup>25</sup> No attempt was made to establish uniform criteria for timing or type of treatment, if any; the patients and their ophthalmologists made these decisions.

A total of 16 patients were treated shortly after enrollment; 20 additional patients were treated after the melanoma grew to medium or large size (COMS criteria), and the patients were enrolled in one of the COMS randomized trials. As of June 1996, an additional 47 patients had been treated during follow-up.<sup>25,26</sup>

By June 30, 1996, 27 patients had died. Survival findings are summarized in [Fig. 154.5](#). The estimated 5-year all-cause mortality rate was 6% (95% CI 3–9%).<sup>25</sup> Of 188 patients who were not treated at time of enrollment, 44 had tumors that had grown to medium or large size by February 1997, based on COMS criteria. The estimated 5-year proportion of initially small tumors that grew was 31% (95% CI 23–39%).<sup>25</sup>

**FIG. 154.5** Cumulative percentage of patients in the Collaborative Ocular Melanoma Study (COMS) nonrandomized, prospective study of small choroidal melanoma who had died by the specified times since enrollment. (Reproduced with permission from Collaborative Ocular Melanoma Study Group. Arch Ophthalmol 1997;115:1537–44. © 1997 American Medical Association. All rights reserved.)

## Histopathologic Findings From Enucleated Eyes

The COMS Group had one of the highest rates of diagnostic accuracy ever documented.<sup>30,33</sup> Of 1532 eyes enucleated in the COMS by June 1996, 994 from patients enrolled in the randomized trial for large choroidal melanoma and 536 from patients enrolled in the trial for medium choroidal melanoma, 1527 (99.7%) were confirmed histopathologically by the Pathology Review Committee to harbor choroidal melanoma.<sup>30,33</sup> A detailed description of the characteristics of the 1527 confirmed cases has been published.<sup>33</sup> Key findings include documentation of local tumor invasion: rupture of Bruch's membrane in 88% of eyes; invasion of emissary canals in 55%; retinal invasion in 49%; tumor cells in the vitreous in 25%; invasion of tumor vessels in 14%; and vortex vein invasion in 22% of eyes with vortex veins. Scleral invasion was present in 56%

of eyes and extrascleral extension in 8%. Histopathologic review confirmed that pre-enucleation radiation significantly reduced mitotic activity.<sup>13</sup>

In other published histopathologic investigations of enucleated eyes of COMS patients, silver-stained nucleolar organizer region scores have been evaluated as predictors of later metastasis,<sup>34</sup> transillumination and histologic measurements of tumor dimensions have been compared,<sup>35</sup> and a clear cell variant of choroidal melanoma has been identified.<sup>36</sup>

## Other Published Findings

The multicenter organization of the COMS facilitated referral to a COMS clinical center of cases of choroidal melanoma from most of the United States and from a large part of eastern Canada. The large number of patients screened for the COMS and judged to have choroidal melanoma (totaling 8712 as of July 31, 1998, when accrual halted) provided the largest group of patients with this diagnosis for whom data had been collected systematically at time of presentation in accord with a common protocol. Trends in size of choroidal melanoma and treatments over time were published.<sup>37</sup> The COMS Group reported the first published cases of choroidal melanoma in Native Americans.<sup>38</sup> This large database permits comparison of tumor characteristics at time of screening and diagnosis among different racial subgroups. This information may provide clues for future investigation in epidemiologic and genetic studies of choroidal melanoma.

The COMS Group also published information on surgical and postsurgical complications among the largest group of patients whose eyes had been enucleated because of choroidal melanoma and who had been examined in accord with a common follow-up protocol,<sup>18</sup> documenting the low rates of serious complications following enucleation for this condition. The importance of liver function tests and other tests for metastasis was evaluated; those findings were published in the oncology literature.<sup>39</sup> Also, 10-year changes in fellow eyes of patients enrolled in COMS randomized trials have been reported.<sup>40</sup> Echographic characteristics of melanoma at baseline<sup>41</sup> and postbrachytherapy changes observed

on fluorescein angiograms and stereoscopic photographs<sup>42</sup> have been published. In addition to publications from the COMS Group that have important clinical information, several articles have been published that deal with research methodology.<sup>43–48</sup>

## Conclusion

The COMS Group successfully enrolled sufficient numbers of eligible patients with choroidal melanoma so that valid comparisons between treatments could be made for mortality and other important clinical outcomes and, in the case of the trial for medium tumors, also on important patient-reported (“quality of life”) outcomes. Protocol adherence and data quality were exceptionally good in both randomized trials. Findings regarding primary and secondary outcomes have been published. The information in [Figs. 154.2](#) and [154.4](#) is useful for patient counseling. The COMS Archives Committee continues to receive and review requests to access archived COMS data.

## Prognosis

## Conclusion

# Introduction

Choroidal metastases are the most common of adult intraocular tumors.<sup>1,2</sup> Autopsy studies suggest that approximately 10% of cancer patients have ocular metastases, most frequently to the choroid.<sup>1,3</sup> Pathologies such as breast cancer are associated with higher rates, approaching 40% late in the course of the disease.<sup>4</sup> Of the cases, 20–40% are bilateral, and multifocal involvement of one eye occurs in approximately 20% of affected cases.<sup>5</sup> Frequency of metastases does not differ for the right or the left eye.<sup>5</sup>

# Symptoms and Clinical Findings

Intraocular metastases may be asymptomatic. When symptomatic, choroidal metastases cause painless visual loss by involvement of the macular area or peripapillary retina or because of an associated, generally exudative, retinal detachment.<sup>6,7</sup> Retinal detachment may cause visual deficits, floaters, and flashes. Larger retinal detachments may be associated with peripheral field deficits. Tumors located anteriorly may tilt the lens, thereby causing visual loss. Rarely, these patients may have painful visual loss as a result of neovascular glaucoma or metastatic iritis.

In a review of 70 patients with choroidal metastases, symptoms at presentation included blurred vision in 80%; pain in 14%; photopsias in 13%; red eye and floaters in 7%; field defects in 3%; and photophobia in 1%. Six percent of patients were asymptomatic.<sup>8</sup>

The most common location for choroidal metastases is the posterior pole of the globe. Up to 40% of lesions have been reported

to be in the macular region.<sup>9</sup> The reason for this may be due to differential blood flow to that area, although macular metastases are also more likely to be symptomatic, therefore increasing the likelihood of diagnosis.

In contrast to choroidal melanomas, which are generally darkly pigmented, choroidal metastases more commonly present as yellow or white lesions (Fig. 155.1). For lesions of a comparable basal size, choroidal metastases are often flatter than choroidal melanomas. Serous retinal detachment is commonly associated and frequently not in proportion with the tumor size.<sup>8,10</sup>

**FIG. 155.1** Elevated, 3-mm, creamy yellow lesion in the macular area. The patient has a known history of breast cancer. A surrounding serous retinal detachment is present.

## Frequency of Primary Cancer Site

The relative frequency of primary cancer sites for patients with choroidal metastases varies by gender. A series of more than 500 patients from the Wills Eye Hospital<sup>11</sup> revealed primary sites for women as follows: breast, 68%; lung, 12%; unknown, 12%; gastrointestinal, 2%; skin, 1%; renal, <1%; and other, 4%. For men, primary sites were lung, 40%; unknown, 29%; gastrointestinal, 9%; prostate, 6%; renal, 6%; skin, 4%; breast, 1%; and other, 4%.

## Diagnostic Evaluation

## Differential Diagnosis

Bilateral or multifocal findings are important clues to the diagnosis, since many simulating lesions tend to be unilateral and unifocal. Unilateral lesions are harder to diagnose. An extremely important diagnostic clue, if present, is a history of a known primary tumor. Many lesions may be confused with choroidal metastases, e.g., choroidal melanoma, choroidal osteoma, choroidal hemangioma, choroidal neovascularization with disciform scar, posterior scleritis, and other rare lesions.

Metastatic tumors usually have a creamy yellow appearance; purely amelanotic lesions are more likely to represent amelanotic choroidal melanomas. Metastatic lesions are usually flatter and rarely show the mushroom-shaped configuration that is often seen with melanomas. Choroidal metastases are also generally located in the posterior pole. Metastatic lesions anterior to the equator and metastases that involve the ciliary body are uncommon, and therefore amelanotic choroidal melanoma is more likely to be diagnosed in those locations. Bilateral or multifocal lesions are more likely to be metastatic, infectious, or uveitic. Combined A- and B-scan ultrasonography is of value in differentiating metastases from primary choroidal melanomas. Choroidal melanomas usually have low to moderate internal reflectivity, whereas metastatic lesions usually have higher internal reflectivity.<sup>12,13</sup> More recently, optical coherence tomography has become useful to assist with the differential diagnosis of choroidal tumors.<sup>14</sup>

Choroidal osteomas may be bilateral and may have a color similar to that of metastatic tumors. Osteomas are rarely significantly elevated, and associated choroidal neovascularization is more common in patients with choroidal osteomas than in those with metastases. Ultrasound examinations<sup>15</sup> and computed tomography (CT) scans are extremely valuable diagnostic tools in these patients because the bony change in the choroid shows very high reflectivity on ultrasound examination, and bone density can be confirmed with the CT scan.<sup>16</sup> Optical coherence tomography (OCT) may show overlying photoreceptor changes.<sup>17</sup>

Circumscribed choroidal hemangiomas are almost always unilateral and unifocal. Their characteristic reddish-orange coloration is an important diagnostic clue. Fluorescein angiography

shows more prominent early choroidal filling than is usually seen with metastatic lesions.<sup>16</sup> OCT features of hemangioma have also been reported.<sup>18</sup>

Although some inflammation may be associated with a choroidal metastasis, inflammation is generally not prominent, but it can be seen, sometimes associated with choroidal detachment.<sup>19</sup> A number of inflammatory conditions should be distinguishable, including Harada disease, the uveal effusion syndrome, posterior scleritis, and similar entities.<sup>16</sup> In these patients, associated vitreous inflammation is often seen, and diffuse thickening of the choroid usually can be demonstrated on ultrasound examination.

Rarely do patients with large disciform scars or subretinal hemorrhages present a confusing picture. There is usually a history of previous visual loss related to choroidal neovascularization, and a history of systemic cancer is much less common. Drusen are usually apparent in the fellow eye. The echograms may be difficult to interpret, and the eyes are occasionally enucleated owing to a mistaken diagnosis of choroidal melanoma.<sup>20</sup> The whitish-yellow color of choroidal metastases is usually quite different from the darker appearance of these lesions, in which admixed blood is a prominent feature.

## Ophthalmic Evaluation and Ancillary Tests

The ophthalmic evaluation should begin with a good general history, since the majority of patients will already have an established primary cancer diagnosis. A complete eye examination, including a dilated fundus examination, is essential. Although one eye may have an obvious lesion, care must be taken to scrutinize the other eye, as the disease is bilateral in 20–40% of patients.

Anticipating that radiation therapy may be recommended and may be cataractogenic, the status of the lens should be carefully evaluated.<sup>21</sup> If the patient is diabetic or has retinal microangiopathy, this should be noted because radiation therapy exacerbates preexisting retinal vascular disease (see [Chapter 61, Radiation retinopathy](#)). Documentary fundus photographs should be obtained to compare with later examinations to assess growth or treatment response.

## Fluorescein Angiography

Fluorescein angiography is rarely useful as an aid in the differential diagnosis of metastatic choroidal tumors because it does not allow the definite differentiation of pseudometastatic lesions such as choroidal hemangiomas or melanomas. Angiography is more helpful in assessing the size of the lesion. Relatively flat areas of choroidal invasion are difficult to recognize clinically, but there is almost always some alteration in the overlying pigment epithelium, which is often highlighted on the angiogram.

Metastatic choroidal tumors are usually hypofluorescent in the early phases of the study and become progressively hyperfluorescent in late phases (Figs. 155.2 and 155.3). The so-called double circulation pattern, thought to be characteristic of choroidal melanomas that have broken through Bruch's membrane, is a rare finding in metastatic tumors.<sup>22</sup> Prominent early choroidal filling is a feature more typical of circumscribed choroidal hemangiomas.<sup>16</sup>

**FIG. 155.2** (A,B) Fluorescein angiographic frames of the lesion in Fig. 155.1.

**FIG. 155.3** (A) Early venous phase angiogram of a small metastasis along the superotemporal arcade from a prostatic primary. Most of the lesion is relatively hypofluorescent. (B) In the late angiogram, the tumor hyperfluoresces. Visual loss is due to serous macular detachment (*arrow*).

## A- and B-Scan Ultrasonography

B-scan ultrasonography is of value in evaluating patients with media opacities or bullous retinal detachments when a choroidal lesion is suspected but cannot be clearly seen. The B-scan ultrasonogram shows an echogenic subretinal mass with diffuse, ill-defined borders. Overlying retinal detachment is common, and sound attenuation in the lesion is usually moderate.<sup>13</sup> In unusual cases, choroidal detachment may be seen.<sup>19</sup>

The A-scan ultrasonogram usually demonstrates moderate to high internal reflectivity. Vascularity is not prominent, and the consistency is solid.<sup>12,13</sup> It is useful to determine the height of the metastatic tumor by ultrasonography so that shrinkage of the lesion can be documented after treatment. A more complete discussion of the ultrasonographic features of choroidal metastases is provided in [Chapter 11 \(Diagnostic ophthalmic ultrasound\)](#), as well as in standard texts.<sup>15</sup> Magnetic resonance imaging and spectroscopy may also prove to be valuable differential diagnostic aids.<sup>23,24</sup>

## Optical Coherence Tomography

OCT imaging, particularly with enhanced depth imaging (EDI) of the choroid as popularized by Spaide and others, may help with the

differential diagnosis. Torres and colleagues have recently summarized the EDI features of various choroidal tumors.<sup>25</sup>

## Fine-Needle Aspiration Biopsy

Diagnostic fine-needle aspiration biopsy (FNAB) of intraocular tumors should be considered only under special circumstances.<sup>26</sup> The technique may be appropriate in a patient who has what appears to be a characteristic metastatic tumor but in whom a primary lesion cannot be found despite an extensive systemic evaluation. Augsburger and Shields<sup>26</sup> include, as an additional indication, the use of the technique in some patients who refuse treatment without histopathologic verification of the lesion (rare) or in patients who have lesions that present major diagnostic uncertainty.

In general, oncologists require a histologic diagnosis before initiation of treatment of nonocular sites. Because of the potential threat to vision, it is not a routine procedure to biopsy intraocular lesions before treatment. Useful reports provide updates on FNAB and choroidal tumors.<sup>27-29</sup>

## Systemic Evaluation

Two-thirds of choroidal metastases are diagnosed in patients with a prior history of malignancy.<sup>11</sup> Of the remaining patients, the primary site of malignancy was subsequently detected in about half, with approximately 70% originating from lung cancer. This high prevalence of lung primaries is likely due to the increased propensity of lung cancer to present with brain/eye metastases relative to other malignancies. In general, the workup for a patient with a known malignancy will vary depending on the location and status of the primary tumor, as well as a history of prior metastatic disease. The staging evaluation should include an MRI of the brain since studies have suggested central nervous system metastases may develop in close to 30% of patients.<sup>5</sup> In addition, it often consists of laboratory data, including serum chemistries, liver function tests, alkaline phosphatase, chest computerized tomography, and bone scan.

## Unknown Primary Site

A patient without a known history of malignancy must undergo a systemic workup to attempt to localize the primary. Because the most common primary site is breast in women and lung in men, breast imaging and chest computerized tomography are important. Blood work including serum chemistries may be useful to evaluate for additional sites of metastatic disease requiring further evaluation or imaging. If a primary tumor is identified, pathologic confirmation of the primary tumor is critical. An evaluation of treatment for the primary tumor including chemotherapy, radiotherapy, or hormonal therapy should be made.

If the choroidal lesion remains the only site of disease following a systemic evaluation, a decision must be made regarding the safety of biopsy of the choroidal lesion.<sup>30,31</sup> Pathologic diagnosis may be helpful in identifying the primary site of disease.

## Management

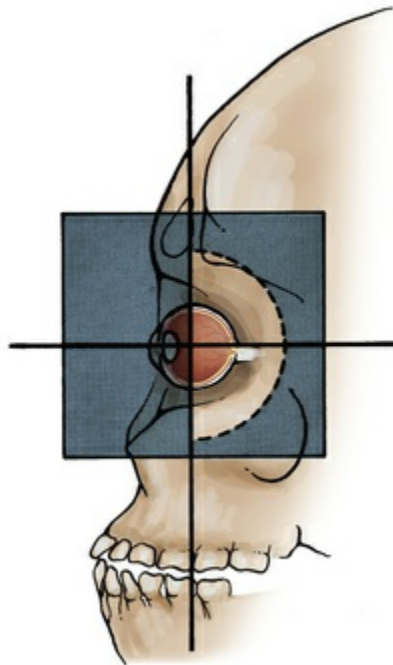

Treatment of patients with choroidal metastases benefits from multidisciplinary collaboration and careful evaluation of multiple factors including the intraocular site, presence of visual symptoms, primary tumor histology and site, presence and status of other metastases, and anticipated efficacy of systemic treatment options. Close observation may be considered for small metastases in the periphery of the retina that may not enlarge rapidly or lead to visual symptoms.<sup>5</sup> Similarly, rapid or complete response to systemic therapy especially in patients with breast or lung cancer may allow postponement or avoidance of local therapy to the choroidal metastases. There are case reports suggesting a potential benefit of crizotinib in ALK-mutated non-small-cell lung cancer.<sup>32,33</sup> By contrast, lesions causing visual symptoms or encroaching upon the optic disc or macula generally require local therapy. Some reports suggest improved outcomes with a combination of local and systemic therapies.<sup>34</sup> Although there was previously interest in intravitreal bevacizumab as a potential therapeutic modality, a recent report suggests progression in an unacceptably high number of patients.<sup>35</sup> The following section addresses radiotherapeutic

management options for choroidal metastases.

## Conventional External Beam Radiation Therapy

Historically, the conventional local treatment for choroidal metastases has been external beam radiation therapy using megavoltage photons. Treatment planning for modern external beam treatment begins with CT simulation to delineate the target as well as adjacent normal tissues. The patient is positioned in a supine position on a flat table with a mask fitting over the face and shoulders for immobilization. The treatment field depends on the location and geometry of the tumor. Modern external beam radiation treatment generally utilize intensity modulated radiation therapy (IMRT) techniques in which inverse planning and multileaf collimators are used to deliver the prescribed dose to the tumor while limiting exposure to the immediately adjacent normal tissues. At present, conformal techniques are preferable and should be considered the standard of care. However, in cases where treatment delays as a result of labor-intensive treatment planning and quality assurance measures are deemed to be inappropriate due to symptomatic progression, conventional treatment plans may be utilized. Since approximately 80% of tumors are located in the posterior segment of the uvea,<sup>36,37</sup> it is generally possible to use a D-shaped field designed to cover the posterior globe, bony roof, floor of orbit, and a portion of the optic nerve but shield the cornea and lens (Fig. 155.4). It may not be possible to block the lens if the metastasis is anterior to the equator. For unilateral metastases, it is possible to achieve adequate coverage with only a single ipsilateral beam. The minimal exit dose to the contralateral globe does not preclude subsequent treatment for development of contralateral metastases. As long as the dose to the contralateral orbit is limited in the initial field, it is relatively simple to treat the contralateral orbit as needed at a later date. A total of 20–40% of patients have bilateral choroidal metastases requiring treatment of both globes.<sup>8,10</sup> The dose typically used for palliation is 3000 cGy in 300 cGy per fraction delivered as a single fraction 5 days per week for 10 treatments. If prolonged survival is anticipated, treatment to a

higher dose of radiation is administered to improve long-term local control. Doses of 4500–5000 cGy in fractions of 200–250 cGy have been reported.<sup>38–43</sup> Local control with these regimens is excellent.

**FIG. 155.4** Conventional D-shaped field used to treat choroidal metastases of the posterior globe, but shield the lens and cornea. CT-based planning is used for target delineation.

## Brachytherapy Plaques

An alternative local therapy for choroidal metastases involves plaque brachytherapy; radioisotopes such as iodine-125, ruthenium-106, or palladium-103 are temporarily surgically placed adjacent to the lesion designed to cover the tumor plus 2–3 mm margin. These treatments typically last about 3 days, after which the plaque is removed. Data to support plaque brachytherapy may be extrapolated from choroidal melanoma in which the technique is believed to have comparable survival to enucleation.<sup>44</sup> A large series of 650 melanoma cases was reported by the Wills Eye Hospital.<sup>45</sup> Local recurrence was 14% at 5 years and 24% at 10 years.

Plaque brachytherapy may be used only for patients with solitary choroidal metastases. In addition, they must have lesions of

appropriate size, depth, and location relative to the macula and fovea. A major disadvantage of this approach is that it involves hospitalization and two surgical procedures for placement and removal of the brachytherapy plaque. (For additional information concerning melanoma-related brachytherapy, the reader is referred to [Chapter 149, Brachytherapy for choroidal melanoma.](#))

## Stereotactic Radiosurgery

Stereotactic radiosurgery (SRS) utilizes multiple precisely focused small radiation beams and high doses for a limited number of fractions. This technique administers ablative doses of radiation to a small volume, thereby maximizing local control while sparing critical adjacent normal tissues. There are multiple technologies that may be used to deliver SRS, including linear accelerator-based approaches or gamma-knife. When using conformal radiation techniques, precise and reproducible immobilization of the eye is critical. Several techniques exist. For example, eye gaze may be directed by asking the patient to visualize a flashing light at a set position. A light field projected onto the sclera may be used to ensure that the gaze during treatment planning matches the treatment setup. The positioning is then verified by an ophthalmologist.<sup>46</sup>

A series from China reviewed patients treated with gamma knife radiosurgery for orbital tumors.<sup>47</sup> Of the 202 cases included, 18 had malignant choroidal tumors. Vision was preserved in 129 patients, with 72 experiencing improvement in vision and 18 experiencing deterioration.

Gamma knife radiosurgery utilizes 201 individual cobalt-60 sources in a collimator to which the patient is adhered using an invasive frame for immobilization. The radiation beam is focused by different-sized collimators, which are controlled by a program that allows them to be quickly changed. Gamma knife is extremely accurate and may be used to treat small lesions ([Fig. 155.5](#)).

**FIG. 155.5** Gamma knife radiosurgery. A frame is invasively attached to the patient's skull for precise stereotactic planning. The treatment helmet contains 201 individual cobalt-60 sources.

An alternate technology is linear accelerator-based radiosurgery, which involves delivery of radiation using either multiple arcs and special collimators to focus the beam or a micromultileaf collimator. Contemporary image-guided radiation therapy (IGRT), in which treatment machines have onboard kilovoltage or megavoltage imaging capabilities, allows confirmation of lesion localization.

## Charged Particle Therapy

A final treatment option for choroidal metastases is proton beam or charged particle irradiation in which charged particles are used to deliver radiation with a very sharp dose fall-off, allowing a potential improvement in vision preservation over conventional radiation therapy. Like radiosurgery, it typically allows for fewer treatments than conventional radiation therapy. A retrospective series from Harvard<sup>47</sup> included 63 patients treated with protons for choroidal metastases. Tumor regression was documented in 84% of patients, and stable disease was reported in 14%. Resolution of retinal detachment was reported in 82%. Fifty-eight percent of patients had visual acuity at last follow-up of 20/200 or better. A recent prospective study performed at the University of California

San Francisco randomized patients with choroidal or ciliary body melanoma to plaque brachytherapy versus charged particle therapy.<sup>48</sup> At a median follow-up of greater than 12 years, they reported a significant benefit in local control in patients receiving charged particle therapy. Specifically local control at 5 years was 100% versus 84% and at 12 years was 98% versus 79% for charged particle and plaque brachytherapy, respectively. While these data do not directly relate to choroidal metastases, they suggest a potential benefit of charged particle therapy over brachytherapy that merits consideration. (More detail on proton beam treatment is included in [Chapter 150, Charged-particle irradiation of uveal melanoma.](#))

## Toxicity

### Ocular Toxicity

Ocular radiation therapy is well tolerated, with minimal acute toxicities,<sup>43,49</sup> including dry eye, epiphora, or irritative symptoms. These symptoms may be managed with artificial tears or lubricating ointments. Topical antibiotics may be indicated for epithelial damage. Long-term ocular toxicity includes cataract formation, which was reported in 3% of patients in one series.<sup>50</sup> Cataract formation is expected if the lens is not shielded and there is a reasonable period of survival following treatment. Damage to the retina and optic nerve are the primary toxicities resulting in reduced visual acuity. Because the dose to critical structures (optic nerve and macula) is below the known radiation tolerance and due to the relatively poor prognosis of patients with choroidal metastases, many patients do not survive to develop radiation retinopathy,<sup>51</sup> which has a median onset of 18 months to 2 years.<sup>2,8,52</sup> A large series using conventional radiation therapy reported retinopathy and optic neuropathy in 2% of patients.<sup>50</sup>

### Nonocular Toxicity

Nonocular toxicities are generally minimal but may include erythema, dry skin, or loss of eyelashes or eyebrows. Facial bone

and muscle growth may be affected in children treated with external beam radiation therapy but should not be affected in adults. Use of certain concurrent chemotherapy with agents such as actinomycin D or doxorubicin should be avoided as they increase the risk of toxicity.

## Prognosis

Development of choroidal metastases usually represents advanced systemic disease<sup>53</sup> with limited potential for cure. Studies suggest a median survival of approximately 16 months,<sup>42,47,54,55</sup> with survival varying by primary tumor type as well as the availability of effective systemic chemotherapeutic options.

Most choroidal metastases respond to local therapy with response rates of approximately 80% in some series.<sup>49,56</sup> Local response is often associated with tumor flattening (Fig. 155.6) and pigmentary proliferation. Improved response rates were associated with (1) symptoms for <49 days prior to initiation of radiation therapy and (2) small tumor extent less than half of a quadrant with minimal or no retinal detachment.<sup>49</sup>

**FIG. 155.6** (A) Fundus appearance of metastatic tumor before treatment. The angiogram from this patient is illustrated in Fig. 151.3. Small tumor deposits (*arrow*) are present in subretinal fluid surrounding the inferior aspect of the tumor. (B) Higher-magnification view. (C) The tumor has flattened completely 1 month after external beam radiation.

Globe preservation is possible in the majority of patients and complete resolution of visual symptoms has been reported in 25–50% of patients.<sup>5,8,10</sup> Time to improvement of visual symptoms

ranges from a few days to 10 weeks following initiation of radiation therapy and typically persists for the remainder of the patient's life.<sup>38</sup>

## Conclusion

Choroidal metastases are the most common intraorbital tumors, with malignancies such as breast and lung cancer being the most common primary sites. Primary management for symptomatic or progressive lesions requires radiation therapy for vision preservation. There are multiple radiation techniques that are associated with high rates of local control and low risk of toxicity. The prognosis of patients with choroidal metastases is poor since most patients will succumb to widely disseminated systemic disease.

### General Considerations

The presence of bone within the eye is unusual and can develop in several clinical settings.<sup>1</sup> Calcification can occur in tissues that are accessible to body fluids, and the process of ossification occurs when an abundant blood supply is present to deliver osteoblasts to organize the architecture of Haversian systems.<sup>2,3</sup> The choroid and the retinal pigment epithelium are the most common sites for bone formation within the eye. Intraocular ossification most often occurs as a dystrophic process in association with phthisis bulbi.<sup>2-5</sup>

Choroidal osteoma is an unusual form of benign intraocular ossification.<sup>1,6-12</sup> In contrast to other types of intraocular ossification, this tumor is found in otherwise healthy eyes. Interest in this tumor was stimulated following enucleation of a presumed amelanotic choroidal melanoma in a 26-year-old woman that proved on histopathology to represent a choroidal osteoma.<sup>8</sup> In 1978, Gass and coworkers described the clinical and angiographic features of choroidal osteoma in a series of 4 patients.<sup>9</sup> Later, three relatively large series on choroidal osteoma by Gass,<sup>10</sup> Aylward et al.,<sup>11</sup> and Shields et al.<sup>12</sup> clarified the clinical and imaging features of this tumor as well as anticipated outcomes. Over four decades, numerous clinical case descriptions of choroidal osteoma have appeared in the literature.<sup>11-52</sup>

### Definition and Incidence

Choroidal osteoma is a benign tumor composed of mature bone. It is typically found in healthy young females in the second or third decades of life<sup>1,10-12</sup> (Fig. 156.1). However, some males,<sup>10,16,35,37,46</sup> young children,<sup>21,23,24,34,38,40</sup> and adults over age 30 years<sup>12,15,21,32,46,50</sup> have been found with choroidal osteoma. There is no predilection for race. Most reported patients with this lesion are Caucasian, but several patients of African American<sup>24,31</sup> and Oriental descent<sup>26,32,34,38,46,50,51</sup> have been described. The tumor generally occurs sporadically; however, there are cases of familial choroidal

osteoma.<sup>21,23,40</sup> The familial cases have been described in a mother and daughter,<sup>21</sup> a brother and sister,<sup>40</sup> and three siblings.<sup>23</sup>

**FIG. 156.1** Clinical spectrum of choroidal osteoma. (A) Unilateral osteoma in a young woman. (B) Unilateral osteoma in a young man. (C) Calcified choroidal osteoma with bone excavation in the macula. (D) Macular choroidal osteoma with decalcification in a young woman.

In our practice of ocular oncology, we have seen approximately 18,000 patients with uveal melanoma over the past 40 years and only approximately 120 patients with choroidal osteoma. Therefore, it is presumed that choroidal osteoma is extremely rare.

## Clinical Features

Patients with choroidal osteoma are often asymptomatic. Symptoms can include visual loss, metamorphopsia, and visual

field defects corresponding to the location of the tumor.<sup>1,10-12</sup> In one report, total blindness of both eyes was found in a young girl with bilateral choroidal osteomas.<sup>43</sup>

Choroidal osteoma is unilateral in approximately 75% of reported cases.<sup>1</sup> In bilateral cases, the tumors can appear symmetric or asymmetric, in different stages of development, growth, or decalcification<sup>10-12</sup> (Fig. 156.2). In one case with 45 years of follow-up, bilateral choroidal osteomas lead to disparate outcomes with poor vision in one eye and retained vision in the other.<sup>52</sup> Rarely, patients with initially unilateral choroidal osteoma can later develop bilateral disease.<sup>30</sup>

**FIG. 156.2** Bilateral choroidal osteoma. (A,B) Small calcified osteomas in macula of young man. (C,D) Larger partially calcified osteomas in a young woman. (E,F) Partially decalcified choroidal osteoma in right eye with subretinal hemorrhage and completely calcified osteoma in the left eye of a young woman.

Choroidal osteoma tends to be located in the juxtapapillary or peripapillary area, often with extension into the macula (Fig. 156.1). Rarely, this tumor is confined to the macular region only, without involvement of the juxtapapillary area.<sup>10-12,16,32,35</sup> Choroidal osteoma is rarely seen in other locations of the eye and, to our knowledge, it has not been known to occur as a solitary lesion anterior to the retinal vascular arcades. Quite often choroidal osteoma is confused with idiopathic sclerochoroidal calcification, a benign, often multifocal, bilateral process that typically occurs anterior to the retinal vascular arcades, near the equator of the eye.<sup>53,54</sup>

The choroidal osteoma appears yellow–orange in color, particularly when the tumor is fully calcified. Over time, as decalcification occurs, the tumor becomes more pale yellow with overlying retinal pigment epithelial thinning and clumping. Choroidal osteoma ranges in size from approximately 2 to 22 mm in basal dimension and approximately 0.5–2.5 mm in elevation.<sup>1,10-12,52</sup> In some cases, the bony tumor surface is irregularly excavated (Fig. 156.1) or elevated. The tumor shape is generally oval or round with characteristic well-defined scalloped or geographic margins. The margins can have blunt pseudopod-like projections. In some instances the tumor can be bilobed with two large plaques joined together by an isthmus.<sup>10,30</sup>

The vasculature within the choroidal osteoma is often visible as tufts of short branching vessels that originate deep within the tumor and emerge onto the tumor surface. This is most prominent over the pale yellow portion of the tumor where the retinal pigment epithelium is thinned and depigmented.<sup>9</sup> These large caliber vessels are not neovascular tissue and are not associated with subretinal exudation or hemorrhage.<sup>1,10</sup> The overlying retinal vasculature and optic disc is characteristically unaffected by the osseous tumor, and there are no related vitreous or anterior segment abnormalities.

Many choroidal osteomas show evidence of slight enlargement in basal dimensions over several months to years<sup>11,38,41,44,48,52,55</sup> (Fig. 156.3). Aylward and associates found tumor growth in 41% of 22 cases over a mean follow-up of 10 years.<sup>11</sup> Shields and associates found tumor growth of 74 choroidal osteomas at 22% by 5 years and 51% by 10 years.<sup>12</sup> In some cases the tumor has doubled in size.<sup>10,41</sup> Others have observed the development of a new choroidal

osteoma in a previously unaffected eye.<sup>1,10</sup>

**FIG. 156.3** Documented enlargement (A,B) of choroidal osteoma over 6 years.

Trimble, Schatz, and Schneider reported a case of a choroidal osteoma in a 23-year-old woman whose tumor enlarged slowly over 5 years.<sup>47</sup> She developed choroidal neovascularization that was treated with photocoagulation, and subsequently the tumor decalcified over 18 months, leaving an atrophic bed. Partial or complete decalcification of choroidal osteoma has been found to occur in 28% of cases by 5 years and 46% by 10 years.<sup>12</sup> Subtle gradual alterations in tumor color, surface pigmentation, and surface contour have also been observed.

Serous subretinal fluid can occur overlying choroidal osteoma. Subretinal fluid usually occurs over the macular portion of the osteoma. Ophthalmoscopy, fluorescein angiography, indocyanine green angiography, and optical coherence tomography should be performed for detection of choroidal neovascular membrane (CNVM).<sup>10-12</sup>

CNVM overlying osteoma has been found in 31% of cases by 5 years, 31–47% by 10 years, and 46–56% by 20 years<sup>11,12</sup> (Fig. 156.4 and Table 156.1). The CNVM is usually associated with subretinal fluid or hemorrhage, but it can be detected prior to vascular leakage as a slightly elevated gray–green subretinal tissue.<sup>15,37</sup> Factors that predict the development of CNVM include irregular tumor surface and subretinal hemorrhage<sup>12</sup> (Table 156.2). If the CNVM is

extrafoveal, it can be treated with anti-vascular endothelial growth factor (anti-VEGF) medications, laser photocoagulation, or photodynamic therapy.<sup>11,12</sup> If the CNVM is in the fovea, the potential for subfoveal hemorrhage and disciform scarring often leads to a poor visual outcome.<sup>12,33</sup> For subfoveal (and most extrafoveal) CNVM, we prefer anti-VEGF therapy monthly to resolve the membrane and then consolidation for extrafoveal CNVM with laser or photodynamic therapy.

**Choroidal Osteoma Factors That Predict Tumor Growth, Decalcification, Choroidal Neovascular Membrane, Vision Loss, and Poor Visual Acuity**

Clinical Factor by Multivariate Analysis	RR (95% Confidence Interval)	P Value
Tumor growth	No significant factor	na
Tumor decalcification		
Irregular tumor surface (vs. smooth surface)	9.2 (2.0–43.7)	0.005
CNVM		
Irregular tumor surface (vs. smooth surface)	10.6 (1.1–98.6)	0.04
Tumor hemorrhage present (vs. absent)	15.1 (2.4–93.2)	0.003
Visual loss $\geq 3$ lines	No significant factor	na
VA $\leq 20/200$		
Symptoms present (vs. absent)	8.3 (1.7–40.8)	0.009
Decalcification present (vs. absent)	3.6 (1.2–11.2)	0.03

CNVM, choroidal neovascular membrane; VA, visual acuity.

Data adapted from Shields, Sun, Demirci, et al.<sup>12</sup>

CNVM should be distinguished from the branching vascular tufts seen on the inner surface of the tumor. The latter are not associated with subretinal fluid, hemorrhage, or disciform scar and do not leak fluorescein on angiography as the former. The reason for the occurrence of CNVM in eyes with choroidal osteoma is unknown. It is postulated that the thinned, degenerated retinal pigment epithelium–Bruch's membrane complex overlying the osteoma develop breaks and neovascular fronds from the choroid grow beneath the sensory retina.<sup>27</sup>

## Differential Diagnosis

The ophthalmoscopic features of choroidal osteoma are usually classic, but small lesions can be mistaken for choroidal granuloma,

nevus, melanoma, or metastasis. Other lesions in the differential diagnosis include circumscribed choroidal hemangioma, disciform macular degeneration, posterior scleritis, sclerochoroidal choroidal calcification, and choroidal cartilage of organoid nevus syndrome.<sup>1,53-60</sup>

Amelanotic choroidal melanoma differs from choroidal osteoma in that it has a yellow-brown color, more elevation, and a less well-defined margin. Amelanotic choroidal nevus can be relatively flat like a choroidal osteoma, but nevus has less distinct margins and can have drusen on its surface. Choroidal metastasis tends to have indistinct margins and is often associated with a serous retinal detachment out of proportion to the size of the tumor.<sup>57</sup>

Furthermore, metastatic carcinoma usually occurs in middle age or older patients who have a prior history of malignancy (especially breast carcinoma). An irradiated choroidal metastasis could resemble a choroidal osteoma because the irradiated metastasis appears flat, atrophic, and lacks subretinal fluid. Choroidal hemangioma can occasionally have overlying fibrous and osseous metaplasia that resembles osteoma.<sup>58</sup> However, choroidal hemangioma is characteristically dome-shaped with smooth regular margins and overlying serous fluid with cystoid degeneration of the retina.

Macular degeneration is typically seen in older patients when it occurs in the spectrum of age-related macular degeneration or it is found with other inflammatory, traumatic, or dystrophic fundus findings to suggest the diagnosis. Macular degeneration is usually centered in the macular area and is less commonly in a juxtapapillary location. Posterior scleritis has a typical orange-brown in color with indistinct margins.<sup>17</sup> The symptom of pain with findings of uveitis, choroidal folds, subretinal fluid, and ultrasonographic evidence of thickened sclera with retrobulbar edema aid in the diagnosis.

Sclerochoroidal calcification clinically appears as an irregular calcific plaque within the choroid or sclera<sup>53-54</sup> (Fig. 156.5). The overlying retina and vitreous are normal. These findings can resemble choroidal osteoma, but sclerochoroidal calcification is not typically juxtapapillary and more often occurs along the retinal vascular arcades, appears multifocal, and can occur in patients with

hyperparathyroidism.<sup>54</sup> The linear nevus sebaceous syndrome can manifest a calcified choroid lesion that represents either scleral cartilage or bone.<sup>59-60</sup>

**FIG. 156.5** Sclerochoroidal calcification demonstrating multifocal equatorial calcific choroidal lesions in an older woman. This condition is distinct from choroidal osteoma.

## Pathology and Pathogenesis

Histopathologic features of choroidal osteoma were first observed in 1978 and reported twice by Williams et al.<sup>8</sup> and Gass et al.<sup>9</sup> The mass is composed of dense bony trabeculae with endothelial lined large cavernous spaces and small capillary blood vessels. Osteoblasts, osteocytes, and osteoclasts are present. The intertrabecular marrow spaces contain loose fibrovascular elements, mast cells, and foamy vacuolated mesenchymal cells. The involved choriocapillaris is narrowed or obliterated in most areas. The choroidal melanocytes are displaced inwards toward the choriocapillaris and outwards toward the sclera. The overlying retinal pigment epithelium is focally depigmented and flat in some areas while clumps of pigment granules within melanophages are seen along Bruch's membrane in other areas.

The pathogenesis of the choroidal osteoma is unknown. The

speculated pathogenesis includes possible choristomatous, inflammatory, traumatic, hormonal, metabolic, environmental, or hereditary etiology.<sup>1</sup> Noble suggested that there might be a congenital, possibly inherited, abnormality of the juxtapapillary choroid that predisposes the patient to the development of this tumor.<sup>40</sup>

The choroidal osteoma resembles a choristoma in its tissue composition, onset in youth, and absence of other preceding ocular disease processes. Osseous choristomas are well-known to occur in the epibulbar region of the eye.<sup>61</sup> The embryologic development of the region of the optic nerve head is complicated, and several congenital hamartomas are found in this region such as the astrocytic hamartoma, combined retinal–retinal pigment epithelial hamartoma, retinal capillary hemangioma, and others. Features of this tumor atypical for a choristoma are the sexual preponderance in females and the rare occurrence of new tumor in previously normal tissue. Bone throughout the body is constantly being remolded and reshaped in adulthood; thus, the change in size of choroidal osteoma does not exclude the potential choristomatous etiology.

Intraocular inflammation has been known to cause dystrophic intraocular calcification and ossification.<sup>62</sup> A focal peripapillary choroiditis could possibly lead to dystrophic calcium deposition and eventually to osteoma.<sup>48</sup> Choroidal osteoma have been reported in children after eosinophilic granulomatosis,<sup>35</sup> sclerouveitis with optic nerve edema,<sup>48</sup> and orbital inflammatory pseudotumor.<sup>31</sup> Although these three cases are well documented, the majority of choroidal osteomas develop in otherwise clinically normal eyes.

Several reports have noted ocular trauma preceding choroidal osteoma.<sup>10,30</sup> Osseous metaplasia of the retinal pigment epithelium may have occurred in these cases; however, the relationship to trauma is speculative.

The occurrence of this tumor predominantly in young adult women raises the question of a hormonal influence.<sup>1,10–12</sup> Most of the women are diagnosed after puberty, but several cases of prepubertal girls have been documented.<sup>10,24,31</sup> Also several male patients have been reported.<sup>14,15,35,37,46,50</sup> Endocrinologic and metabolic workup has been unrevealing. There have been no

consistently abnormal serum calcium, phosphorus, or alkaline phosphatase levels detected in patients with choroidal osteoma. Katz and Gass<sup>31</sup> reported a patient with transient mild secondary hypoparathyroidism (decreased serum calcium and increased serum phosphorus and increased alkaline phosphatase) and multiple choroidal osteomas, but classically parathyroid abnormalities cause a picture of sclerochoroidal calcification,<sup>54</sup> not choroidal osteomas.

Choroidal osteomas were not recognized in the older literature. The possibility that recent environmental toxins, exposures, or drugs may cause this tumor has been suggested. No consistent drug use or geographic location has been found. Choroidal osteoma was misdiagnosed in one prominent textbook, *Tumors of the Eye*, where an illustration of an “ossified choroidal hemangioma” in 1947 actually proved to be choroidal osteoma upon later review.<sup>8,63</sup> It is possible that several cases in the older literature may have been misdiagnosed prior to the description of the choroidal osteoma in 1978.

Cunha in 1984 reported a familial case of choroidal osteomas seen in a 37-year-old mother and her 5-year-old daughter.<sup>21</sup> The mother had poor vision from 11 years old. Eting and Savir in 1992 reported an atypical fulminant course of bilateral choroidal osteomas in a 5-year-old boy and his 7-year-old sister, and both siblings developed severe bilateral visual loss.<sup>23</sup> Noble in 1990 reported bilateral choroidal osteomas in 9-year-old twin brothers and their 11-year-old sister.<sup>40</sup> The mother had a yellow mottled fundus but no clear evidence of osteoma. These three occurrences seem to be more than coincidental for this rare tumor and may indicate a possible hereditary or environmental component for some choroidal osteomas.

## Diagnostic Approaches

### Fluorescein Angiography

Fluorescein angiography of a choroidal osteoma shows mild, patchy early hyperfluorescence of the tumor that evolves to a diffuse intense late staining (Fig. 156.4). The tumor can show early

hyperfluorescence of the vascular tufts without leakage.<sup>1,7,10-12</sup> This fluorescence fades slightly in the later stages of angiography.

Overlying choroidal neovascularization shows lacy early hyperfluorescence with early leakage of dye and late staining of the surrounding tissue. Occasionally there are multiple pin-point leakage sites from the osteoma that are not associated with neovascularization. Areas of persistent hypofluorescence correspond to subretinal hemorrhage or retinal pigment epithelial hyperplasia. Fluorescein angiography of the optic disc and retinal vasculature shows no abnormality.

## Indocyanine Green Angiography

Indocyanine green angiography shows early hypofluorescence of the choroidal mass.<sup>36,51,64</sup> The large caliber choroidal vessels can traverse the peripheral portion of the osteoma and even transect a pseudopod. Fine diffuse fluorescence of the mass is seen by 2 minutes into the study and seems to emanate from ill-defined multifocal points within the area of the mass, perhaps related to the fine perforating vessels of the tumor. The fluorescence gradually becomes confluent and almost isofluorescent in the late frames.

## Ultrasonography

Ultrasonography is useful for differentiating choroidal osteomas from other clinically similar lesions. A-scan ultrasonography demonstrates a high-intensity echo spike from the inner surface of the tumor with decreased amplitude of the orbital soft tissue echoes immediately posterior to the tumor. B-scan ultrasonography demonstrates a slightly elevated, highly reflective choroidal mass that persists at lower scanning sensitivity after the other soft tissue echoes have disappeared. Acoustic shadowing of the orbit occurs just posterior to the choroidal mass, giving the appearance of a pseudo-optic nerve.<sup>1,7</sup>

## Optical Coherence Tomography

Time domain optical coherence tomography (OCT) shows choroidal osteoma as a dense, undulating lesion with deep

shadowing. Overlying choroidal neovascularization, subretinal fluid, retinal edema, retinal thinning, and photoreceptor loss, particularly in areas of decalcification, can be delineated<sup>26,65</sup> (Fig. 156.6). Spectral domain OCT demonstrates greater detail of the choroidal mass.<sup>66-72</sup> Pellegrini et al.<sup>68</sup> and Shields et al.<sup>69</sup> independently observed the presence of bone lamella and spongy appearance of bone within the tumor (Fig. 156.7).

**FIG. 156.6** Optical coherence tomography (OCT) over choroidal osteoma in a patient with bilateral tumors (A,B) that shows prominent submacular decalcification and atrophy in the right eye (A) and preserved calcification/ossification in the left eye (B). On relatively low resolution time domain OCT (C,D) and higher resolution spectral domain OCT (E,F), the irregularity of tumor surface in the right eye is much more than in the left eye.

**FIG. 156.7** Spectral domain optical coherence tomography over calcified osteoma (A) demonstrating horizontal cuts through the mass showing undulating surface of the osteoma (B) with intrinsic linear lamella (*white horizontal lines*) and possible vascular channels (*black lucent tubular regions*). Note the overlying subretinal fluid with shaggy photoreceptors (C).

## Autofluorescence

Autofluorescence shows nonspecific hyperautofluorescence at sites of fresh subretinal fluid or retinal pigment epithelial disturbance.<sup>73–75</sup> In chronic cases with decalcification and retinal pigment epithelial loss, hypoautofluorescence is noted.

## Roentgenography

Roentgenograms of the orbit are not commonly performed, but osteoma appears as a thin plaque of radiodensity on the posterior aspect of the globe.<sup>10,30</sup> Roentgenograms are rarely performed for diagnostic purposes as this mode has been replaced by computed tomography.

## Computed Tomography

Computed tomography of choroidal osteomas shows characteristic features of a radiopaque plaque of bone density at the level of the

affected choroid<sup>1,7</sup> (Fig. 156.8).

**FIG. 156.8** Computed tomography (A) of choroidal osteoma shows calcified plaque in both eyes. The T1-weighted (B) and T2-weighted (C) magnetic resonance images show the flat plaque as bright on T1 and dark

on T2.

## Magnetic Resonance Imaging

Magnetic resonance imaging with surface coil of choroidal osteoma reveals a bright signal on T1-weighted images and relative low intensity on T2-weighted images (Fig. 156.8). On contrast T1-weighted scans, the tumor shows enhancement.<sup>22</sup>

## Radioactive Phosphorus Uptake

The radioactive phosphorus uptake (<sup>32</sup>P) test is generally not performed for intraocular tumors, but it has been used in the past. In a few cases in which it had been performed, the results were strongly positive.<sup>8</sup> The choroidal osteoma can give positive results on <sup>32</sup>P testing because the bone in the tumor accumulates phosphorus and incorporates it into its structure.

## Laboratory Studies

In patients with choroidal osteomas, there have been no consistently detectable abnormalities in complete blood counts, blood chemistries (including serum calcium, phosphorus, and alkaline phosphatase), and urinalysis.<sup>1,10-12</sup>

## Management

The management of choroidal osteoma includes prevention of tumor growth, induction of decalcification of tumor, and treatment of choroidal neovascularization. There is no currently known systemic metabolic or hormonal method for altering the growth of the choroidal osteoma. For choroidal osteoma in the subfoveal region, the goal is to maintain calcification of the mass so that the outer retinal structures remain intact.<sup>54,65</sup> Based on OCT studies, eyes that maintain ossified osteoma generally show intact photoreceptors and intact visual acuity compared to eyes with de-ossified osteoma in which the retinal pigment epithelium demonstrates atrophy and overlying photoreceptor retraction.<sup>65,69</sup>

Some authorities have advocated oral calcium supplements in these cases, but there is no confirmatory study. For osteoma in the extrafoveal region, the goal is to decalcify the mass so that it cannot grow towards the foveola. Decalcified osteoma generally do not grow in the direction of decalcification. Decalcification can be achieved with ablative laser photocoagulation or photodynamic therapy.<sup>1,10-12,76</sup> Our current preferred treatment for extrafoveal osteoma is photodynamic therapy.<sup>76</sup>

Management of related subretinal fluid or CNVM involves anti-VEGF medications on a monthly basis in a “treat and extend” strategy.<sup>77-80</sup> Previous reports on laser photocoagulation and surgical removal of CNVM, but visual recovery was not impressive.<sup>14,19,25,27,29,39</sup> Photodynamic therapy using verteporfin has been found successful for management of extrafoveal CNVM over osteoma<sup>16,65</sup> (Fig. 156.9).

**FIG. 156.9** Small, calcified juxtapapillary choroidal osteoma with choroidal neovascular membrane (CNVM) and subretinal hemorrhage (A,B) treated with photodynamic therapy. The tumor decalcified clinically and by ultrasound, and the CNVM resolved (C,D).

## Prognosis

The visual prognosis is quite varied and unpredictable. Most patients with extrafoveal choroidal osteoma maintain good visual acuity. Some patients with a subfoveal choroidal osteoma retain good visual acuity for months to years. In an analysis of 74 affected eyes, visual loss of 3 or more lines occurred in 26% by 5 years, 45% by 10 years, and 59% by 20 years. Poor visual acuity of 20/200 or worse was found in 14% at 1 year, 45% at 5 years, and 56% at 10

years<sup>12</sup> (Table 156.1). The reason for visual loss included subretinal fluid, subretinal blood, retinal pigment epithelial atrophy or mottling, and photoreceptor atrophy, particularly over decalcified osteomas. Factors that statistically predict poor vision include symptoms and decalcification<sup>12</sup> (Table 156.2). The prognosis for life in the patient with choroidal osteoma is no different from the general population.<sup>1,10-12</sup>

## Conclusions

Choroidal osteoma is a benign ossified tumor of the choroid typically found in healthy young females in the second or third decade of life. It has been reported to exist in males and in children. Choroidal osteoma is unilateral in 75% of cases, tends to be located in the juxtapapillary area, and ranges in size from 2 to 22 mm in basal dimension. It is minimally elevated and may have associated subretinal fluid and choroidal neovascularization.

Choroidal osteoma should be differentiated from choroidal melanoma, choroidal nevus, choroidal metastasis, choroidal hemangioma, and sclerochoroidal calcification. Ultrasonography can demonstrate calcium within the lesion. Fluorescein angiography can demonstrate choroidal neovascularization. Optical coherence tomography can delineate bone lamellae and spongy tissue within the mass and provide an estimate of visual potential.

The pathogenesis of choroidal osteoma is unknown, and there is no known systemic modification to benefit resolution of this tumor. Related choroidal neovascularization is usually treated with anti-VEGF therapy and photodynamic therapy. The visual prognosis is variable, but the systemic prognosis is good.

## Introduction

Choroidal hemangiomas are benign vascular hamartomas that occur in two forms: circumscribed and diffuse. The circumscribed form is typically an isolated finding without systemic associations, while the diffuse form generally occurs in association with Sturge–Weber syndrome (discussed separately in [Chapter 137](#), Phakomatoses). There have been rare reports of circumscribed choroidal hemangioma in patients with Sturge–Weber syndrome.<sup>1,2</sup> The first histologically confirmed case of choroidal hemangioma was published by Leber in 1868.<sup>3</sup> The incidence of the disease is difficult to estimate since most circumscribed choroidal hemangiomas only come to medical attention if patients become symptomatic or if they are discovered incidentally during routine examination; however, the disease is felt to be relatively rare, with

five cases discovered upon histologic examination of 4500 enucleated eyes.<sup>4</sup> More than 90% of reported cases have been in Caucasian patients (though there have been published cases in black, Hispanic, and Asian patients), with a relatively even distribution between males and females.<sup>5,6</sup> The mean age at diagnosis in the two largest case series ranged from 38.7 years to 47 years, considerably older than the mean age at diagnosis for diffuse choroidal hemangioma, which is typically in the first decade of life.<sup>5,6</sup>

## Clinical Features

Circumscribed choroidal hemangiomas are generally orange-red masses found posterior to the equator (Figs. 157.1–157.5). The color of the tumor has also been described as “salmon-colored,”<sup>7</sup> “yellow-white,”<sup>8</sup> and “grayish-pink.”<sup>6</sup> Choroidal thickening may be difficult to discern on color photographs and may be more apparent on clinical examination. Pigmentary changes have also been reported on the surface of the tumor or as a ring of hyperpigmentation around the edge of the tumor.<sup>6</sup> There may be accumulation of lipofuscin pigment (orange pigment) over the lesion most easily seen with fluorescein angiography<sup>9</sup> or fundus autofluorescence.<sup>10</sup> In the largest published series of 200 patients by Shields et al., 67% of circumscribed choroidal hemangiomas were in the macula, 34% were between the macula and the equator, and no tumors were anterior to the equator.<sup>5</sup> In the second-largest series, of 45 patients with these tumors reported by Witschel and Font, all were located posterior to the equator.<sup>6</sup> In the Shields series, the mean tumor diameter was 6.7 mm and the mean tumor thickness was 3.1 mm.<sup>5</sup> Lesions are usually solitary and unilateral, though bilateral choroidal hemangiomas have been reported.<sup>7</sup> Overlying subretinal fluid or serous retinal detachment is a common finding, present in 47% of patients in the Witschel series<sup>6</sup> and 81% of the patients in the Shields series (Fig. 157.3)<sup>5</sup> – although these are biased samples comprised largely of symptomatic patients. Cystoid macular edema is also a common finding, present in up to 17% of patients. Associated exudates, epiretinal membranes, and retinal hemorrhages have also been reported.<sup>5</sup> Exudates are uncommon.

Choroidal neovascularization is rare but has been reported in a small number of patients<sup>5,11-13</sup> Retinal neovascularization has also been reported in three eyes with circumscribed choroidal hemangioma.<sup>14</sup> Patients with total retinal detachments secondary to circumscribed choroidal hemangioma may also develop neovascularization of the iris and angle, and neovascular glaucoma.<sup>5</sup>

**FIG. 157.1** (A) Circumscribed choroidal hemangioma in the left eye of a 54-year-old man complaining of metamorphopsia for 2 months with visual acuity of 20/64. Note the orange-reddish color of the lesion that is similar to surrounding normal choroid. Note also the fine drusen and characteristic pigmentary changes overlying the lesion. (B) Spectral domain optical coherence tomography (right) and confocal scanning laser ophthalmoscopy (SLO, left) (Spectralis, Heidelberg Engineering GmbH, Heidelberg, Germany) images. Note how the SLO image reveals the borders of the hemangioma more clearly than the color photograph. The OCT reveals a sloping choroidal mass elevating the retina associated with mild subfoveal fluid, which likely accounts for the moderate decrease in visual acuity.

**FIG. 157.2** (A) Color fundus photo of a circumscribed choroidal hemangioma in an asymptomatic 66-year-old man with 20/32 acuity. Note the reddish color of the lesion which, in contrast to Fig. 157.1, is of a slightly different color than surrounding choroid. (B) Wide-field color image (Optos plc., Dunfermline, Scotland) of the same lesion as (A). Note how the false color provided by Optos creates a different appearance that makes the tumor difficult to identify. (C) Enhanced-depth imaging spectral domain optical coherence tomography reveals a choroidal mass without overlying subretinal fluid. The hemangioma is located primarily nasal to the fovea and obscures normal choroidal detail. Fine outer retinal changes as well as trace intraretinal fluid are seen near the apex of the tumor. (D) B-scan ultrasonography reveals the lesion to be minimally thick (0.8 mm) and have a high internal reflectivity (similar to nearby normal choroid). (E) Fundus autofluorescence reveals variable hyper- and hypoautofluorescence over the lesion and reveals an inferior hyperautofluorescent area secondary retinal pigment epithelial changes associated with chronic trace subretinal fluid. (F) Fluorescein angiography at one minute (above) shows early diffuse hyperfluorescence that persists into later frames

(below, 3.5 minutes). This lesion was observed and found to be stable over time.

**FIG. 157.3** (A) Color photograph of circumscribed choroidal hemangioma in left eye of 36-year-old patient complaining of photopsias and inferonasal scotoma for one month. (B) Optos macula photograph providing more perspective on the location of the lesion compared to the photograph in (A), but with false color. (C) Spectral domain optical coherence tomography (SD-OCT) showing a choroidal mass and subretinal fluid. (D) B-Scan ultrasonography showing a dome-shaped lesion with high-internal reflectivity measuring 6.61 mm across (transverse) by 2.55 mm thick. (E) Photograph taken 3 months following one session of photodynamic therapy (PDT) showing early pigmentary changes over tumor but otherwise an overall stable appearance compared to baseline photos. Acuity improved to 20/20 with near-resolution of symptoms. (F) SD-OCT image 3 months following PDT showing decreased thickness of choroidal mass, near resolution of subretinal fluid and persistent outer retinal changes. (G) B-Scan ultrasonography 3 months following PDT showing decreased tumor thickness (1.34 mm) and

transverse width (5.07 mm).

**FIG. 157.4** (A) A red–orange choroidal hemangioma superior to the optic disc with a serous detachment into the macula. The tumor thickness is 2.8 mm. (B) Intravenous fluorescein angiography of this tumor shows patchy hyperfluorescence at the time of arterial flow. (C) Late patchy staining of the tumor with some dye leakage into the subretinal space. (D) Ultrasonography of this tumor demonstrates a solid dome-shaped lesion on B-scan and high internal reflectivity with A-scan echography. (E) Sketch of this tumor with subretinal fluid extending into the macula. (F) Overlapping circles show the distribution of the laser applications following infusion of verteporfin. (G) Appearance of this tumor 3 months following photodynamic therapy. The tumor is now flat with some rarefaction of the retinal pigment epithelium and subtle evidence of subretinal fibrosis. (H) Ultrasonographic view of the tumor 3 months after treatment shows no measurable tumor height.

**FIG. 157.5** A solitary hemangioma of the juxtapapillary

choroid is located temporally. Extensive microcystic degenerative changes of the overlying retina are evident (hematoxylin and eosin, ×11).

Circumscribed choroidal hemangiomas usually do not grow, although there have been reports of gradual enlargement.<sup>15,16</sup> In five cases, there was only slight enlargement with a mean of 1.6 × 1.5 mm in basal diameter and 0.9 mm in thickness over an average of 52 months of follow-up.<sup>15</sup> In another case with significant enlargement, the eye was enucleated due to concern for choroidal melanoma and pathologic examination revealed that the increase in size was most likely due to vascular congestion of the tumor vessels, and possibly an increase in the caliber and number of tumor vessels.<sup>16</sup> There has also been one report of “blackening” of a circumscribed choroidal hemangioma from red–orange to dark gray after tantalum clip placement in preparation for external proton beam irradiation.<sup>17</sup> The hemangioma subsequently returned to its original red–orange color 2 weeks after surgery (prior to proton beam irradiation), leading the authors to hypothesize that the transient color change may have been due to extravascular hemorrhage from surgical manipulation.<sup>17</sup> Bosch and Helbig also reported blackening of a choroidal hemangioma after photodynamic therapy.<sup>18</sup>

The most commonly reported symptom is blurred vision in up to 81% of patients, though patients also note visual field deficits, metamorphopsia, and floaters.<sup>5</sup> Presenting visual acuity ranged from 20/20–20/40 in 24% of eyes to 20/400 or worse in 34% of eyes in the Shields series, and 60% of eyes were “blind” in the Witschel series.<sup>5,6</sup>

## Differential Diagnosis

The differential diagnosis of circumscribed choroidal hemangioma includes choroidal nevus, amelanotic choroidal melanoma, choroidal metastasis, choroidal osteoma, and central serous chorioretinopathy. On clinical examination, choroidal hemangiomas have a characteristic orange–red color, unlike choroidal metastases, which are more likely to be creamy-yellow,

and amelanotic melanomas, which tend to be yellow–tan.<sup>5</sup> Ancillary testing is very helpful to distinguish these conditions.

Ultrasonography shows high internal reflectivity in choroidal hemangioma due to the vascular component of the lesion, in contrast to choroidal melanomas, which display low to medium internal reflectivity. Circumscribed choroidal hemangiomas also have a very distinct appearance on indocyanine green angiography with rapid filling and “washout” phenomenon, unlike choroidal melanoma and metastasis, which have slower and less intense filling.<sup>5</sup> On magnetic resonance imaging, circumscribed choroidal hemangiomas show bright signal on both T1- and T2-weighted images, whereas choroidal melanomas and metastases show bright signal on T1-weighted images but low signal on T2-weighted images.<sup>5</sup>

## Ancillary Studies

### Intravenous Fluorescein Angiography

Fluorescein angiography (FA) of circumscribed choroidal hemangiomas generally reveals mild early lacy hyperfluorescence of the tumor in the prearterial and arterial phase, followed by moderate hyperfluorescence during the arteriovenous phase, and increasing hyperfluorescence through the late phase with variable amounts of late leakage (Figs. 157.1, 157.3 and 157.4).<sup>5,19,20</sup> The FA pattern of choroidal hemangioma may be variable and similar to other amelanotic choroidal tumors, hence FA may not be diagnostic in the absence of other ancillary testing.<sup>21</sup> FA can also be helpful for visualization of associated subretinal fluid and cystoid macular edema, which are not typically seen on indocyanine green angiography.<sup>21</sup>

### Indocyanine Green Angiography

Indocyanine green angiography (ICGA) is particularly helpful in the diagnosis of circumscribed choroidal hemangioma since it provides improved visualization of the choroidal vasculature. Circumscribed choroidal hemangiomas usually show a

characteristic rapid onset of fluorescence around 30 seconds, much earlier than in other choroidal tumors.<sup>21-23</sup> This fluorescence occurs in a lacy, diffuse hyperintense pattern that fills peripherally first followed by central filling.<sup>22</sup> In the late frames, the tumor demonstrates loss of dye resulting in a hypofluorescent appearance compared with the surrounding choroid, which is known as the “washout” phenomenon.<sup>21-23</sup> In addition, a late hyperfluorescent rim around the tumor is almost always present.<sup>21-23</sup> Intrinsic tumor vessels are more likely to be seen with ICG than with FA, and the normal choroidal vasculature beneath the tumor is obscured, a feature which is also considered pathognomonic.<sup>21,23</sup> Chronic lesions with significant retinal pigment epithelial changes may have blocked fluorescence on ICGA.

## Ultrasonography

Circumscribed choroidal hemangiomas have a consistent characteristic appearance on ultrasonography (US). On B-scan US the hemangioma appears as an acoustically solid mass, which is almost always identical in character to the surrounding normal choroid (Figs. 157.2–157.4).<sup>5,20</sup> The tumor is typically dome-shaped but can occasionally appear mushroom-shaped or plateau-shaped.<sup>5</sup> On A-scan, the tumor demonstrates high internal reflectivity.<sup>5,20</sup> Both A- and B-scan ophthalmic US are useful to distinguish choroidal hemangioma from choroidal melanoma, as the latter is usually acoustically hollow with medium to low internal reflectivity.<sup>5</sup>

## Neuroimaging

Magnetic resonance imaging (MRI) of choroidal hemangioma typically shows hyperintensity in contrast to vitreous on T1-weighted images, and hyperintensity or isointensity to vitreous on T2-weighted images.<sup>5</sup> Choroidal hemangiomas show enhancement with gadolinium contrast.<sup>5</sup> The MRI findings may be helpful in differentiating from choroidal melanoma and metastasis, which show bright signal on T1-weighted images and low signal on T2-weighted images.<sup>5</sup> Clinically, such studies are rarely used to diagnose this condition.

## Optical Coherence Tomography and Enhanced Depth Imaging

In choroidal tumors, traditional time-domain and spectral domain optical coherence tomography (SD-OCT) are most useful for visualizing secondary changes to the retina and retinal pigment epithelium (RPE).<sup>24</sup> In choroidal hemangiomas, OCT can be used to demonstrate macular edema, epiretinal membranes, and subretinal fluid (Figs. 157.2 and 157.3). Until recently, wavelength-dependent light scattering and decreasing sensitivity and resolution with increased displacement from zero delay prevented detailed imaging of the choroid and sclera with OCT.<sup>25</sup> Spaide and colleagues described a method of placing the SD-OCT closer to the patient to purposefully image deeper layers, producing a detailed inverted image of the choroid.<sup>25</sup> Several authors have used this enhanced depth imaging (EDI) technique to image a variety of choroidal tumors, including circumscribed choroidal hemangioma.<sup>26</sup>

Circumscribed choroidal hemangiomas tend to exhibit a smooth surface with expansion of the medium and large choroidal vessels but without compression of the overlying choriocapillaris.<sup>26-29</sup>

## Autofluorescence

Fundus autofluorescence (FAF) is an imaging technique that visualizes excitation of phosphores, typically from substances such as lipofuscin, distributed in the RPE cell monolayer.<sup>30</sup> FAF is increased in dysfunctional RPE and decreased in areas of photoreceptor loss, and has been useful in age-related macular degeneration (AMD), Best disease, and various chorioretinal inflammatory disorders.<sup>30</sup> A study of FAF in 34 eyes with choroidal hemangiomas (27 of which were circumscribed) found that the intrinsic tumor FAF of untreated circumscribed choroidal hemangiomas was either isoautofluorescent (58%) or hypoautofluorescent (42%), and treated circumscribed choroidal hemangiomas were all hypoautofluorescent (100%).<sup>31</sup> The extrinsic FAF of the overlying retinal pigment epithelium and retinal alterations showed hyperautofluorescence of orange pigment in two cases of untreated

circumscribed choroidal hemangioma, and hypoautofluorescence of RPE hyperplasia, atrophy, and fibrous metaplasia<sup>31</sup> (see Fig. 157.2).

## Pathology

Choroidal hemangiomas are considered hamartomas, which are defined as benign vascular tumors composed of tissue elements normally found in the location of the tumor. Hemangiomas of the choroid are classified histopathologically according to the prevailing type or types of vessels within the tumor: capillary, cavernous, or mixed.<sup>6</sup> The capillary type is composed of small vessels separated by loose connective tissue (Fig. 157.6), whereas the cavernous type is composed of larger vessels separated by relatively little connective tissue (Fig. 157.7). The mixed type shows both capillary and cavernous features. Choroidal hemangiomas are notable for the lack of cellular proliferation of the elements of the vessel walls, supporting the idea that these tumors are nonproliferative lesions.<sup>6</sup>

**FIG. 157.6** Capillary type of choroidal hemangioma showing uniformly small vessels separated by a loose, edematous, intravascular stroma. The retina (upper right) is detached and cut obliquely through the plane of the nerve fiber (hematoxylin and eosin,  $\times 50$ ).

**FIG. 157.7** Cavernous type of choroidal hemangioma with early cystoid changes of the outer plexiform and inner nuclear layers. The dilated, blood-filled spaces are lined with a flat layer of endothelial cells with minimal intervascular stroma. Proliferation of retinal pigment epithelial cells is present (hematoxylin and eosin,  $\times 50$ ). (Reproduced with permission from AFIP and Witschel H, Font, RL. Hemangioma of the choroid. A clinicopathologic study of 71 cases and a review of the literature. *Surv Ophthalmol* 1976;20:415–31.)

Witschel and Font, using the files of the Armed Forces Institute of Pathology (AFIP), studied 45 eyes containing a circumscribed choroidal hemangioma.<sup>6</sup> They found 20 tumors of the cavernous type, 22 tumors of the mixed type, and only 3 of the capillary type.<sup>6</sup> This finding is in contrast to the diffuse type of choroidal hemangioma associated with Sturge–Weber syndrome, in which mixed type tumors were found in all 17 cases studied.<sup>6</sup>

Circumscribed choroidal hemangioma pushes choroidal melanocytes toward the periphery of the tumor, the sclera, and the choriocapillaris. Pigmentation alterations in the overlying retinal pigment epithelium (RPE) are common and may range from

disorganization and proliferation of the RPE to the formation of fibrous plaques on the inner surface of the choroid (Fig. 157.8), which produces a grayish-white appearance over some of these tumors.<sup>6,32</sup> Ossification overlying the tumor may occur secondary to degenerative transformation and proliferation of retinal pigment epithelial cells and is likely a sign of chronicity.<sup>6</sup> Retinal changes overlying circumscribed choroidal hemangiomas may include edema or cystic degeneration, loss of photoreceptors/ellipsoid layer, loss of the external limiting membrane, gliosis, and, occasionally, deposition of lipofuscin or migration of RPE cells into the retina.<sup>6,28,32</sup>

**FIG. 157.8** This fibrous nodule, representing transformation of retinal pigment epithelial cells, overlies a cavernous hemangioma of choroid. A thin plaque of bone (*arrow*) is interposed between the base of the fibrous nodule and the hemangioma. Collections of leukocytes are present in some vessels (hematoxylin and eosin,  $\times 90$ ). 31.)

Histologic studies demonstrate that the orange or orange–yellow spots over the surface of circumscribed choroidal hemangiomas are

lipofuscin contained in macrophages located in both the RPE and the outer plexiform layer,<sup>9</sup> although this occurs with less frequency compared to choroidal melanoma.

Except in those cases of severe secondary glaucoma, the retinal ganglion cells and nerve fiber layer are preserved despite severe retinal changes elsewhere.<sup>6,28</sup> Serous detachments of the retina are not an uncommon finding.

## Treatment

Asymptomatic circumscribed choroidal hemangiomas may be observed.<sup>5</sup> In some cases the hemangioma may be symptomatic only by inducing a hyperopic shift that may be treated with refractive correction alone. Observation may also be indicated in cases of subfoveal tumors that have resulted in hyperopic amblyopia.<sup>5</sup> For symptomatic circumscribed choroidal hemangiomas with exudative retinal detachment or cystoid macular edema, a variety of treatment modalities are available.

## Laser

### Photodynamic Therapy

Photodynamic therapy (PDT) was first introduced to treat symptomatic circumscribed choroidal hemangioma in 2000<sup>33</sup> and is currently considered to be the preferred treatment for tumors with symptomatic exudative retinal detachment or intraretinal fluid (Figs. 157.3 and 157.4).<sup>34</sup> Circumscribed choroidal hemangioma may be particularly amenable to PDT since verteporfin is sequestered preferentially in abnormal large-caliber vessels. In contrast to laser photocoagulation, radiation therapies, and transpupillary thermotherapy, PDT allows relatively selective targeting of choroidal tumor vessels, leading to regression with minimal damage to the overlying retina,<sup>35</sup> although branch retinal artery occlusion has been reported following PDT of circumscribed choroidal hemangioma.<sup>36</sup> For this reason, PDT is also suitable for treatment of subfoveal choroidal hemangiomas.<sup>37</sup> Laser photocoagulation, in contrast to PDT, does not penetrate beyond the surface of the tumor.<sup>38</sup> External beam radiotherapy may induce

tumor regression but carry additional risks (cataract, optic neuropathy, radiation retinopathy) and often require invasive surgeries such as tantalum clip placement for proton beam and plaque placement and removal for brachytherapy (see below).<sup>39–42</sup> PDT is typically performed with administration of intravenous verteporfin at a dose of 6 mg/m<sup>2</sup> before treatment with laser wavelengths of 689, 690, or 692 nm at an intensity of 600 mW/cm<sup>2</sup> with duration ranging from 83–166 seconds (50–100 J/cm<sup>2</sup>) from 5 to 15 minutes following the start of infusion.<sup>43–49</sup> The systemic and ocular safety of PDT has been well documented in the Treatment of Age-Related Macular Degeneration with Photodynamic Therapy (TAP) trial<sup>50</sup> and related studies.

There have been numerous case series of patients with circumscribed choroidal hemangioma treated with PDT. The results of the studies with 10 or more patients are summarized in [Table 157.1](#), which reviews the results of PDT treatments in 201 patients, not including the numbers that have been treated in smaller case series. PDT is increasingly selected as the primary therapy for symptomatic circumscribed choroidal hemangioma.<sup>43,45</sup> In all but two of the case series, the majority of patients received one PDT treatment.<sup>37,38,43–45,47</sup> The two series where the vast majority of patients required more than one PDT treatment were the studies by Schmidt-Erfurth et al. and Porrini et al. where the treatment goal was defined as complete resolution of the tumor, not just resolution of subretinal and intraretinal fluid.<sup>48,51</sup> Follow-up ranged from 1 to 80 months in the 11 studies.<sup>37,38,43–45,47–49,51–53</sup> Treatment protocols and effects varied between the studies. Most series showed stabilization or improvement in visual acuity, reduction in intra- and subretinal fluid, and tumor regression in the majority of patients. While Schmidt-Erfurth et al. and Porrini et al. have suggested that the goal of therapy is elimination of subretinal fluid and tumor regression, most other authors have concluded that tumor elimination is not the ultimate goal and retreatment is only necessary for persistent or recurrent exudation or visual loss.<sup>37,44,48</sup> Higher numbers or intensity of PDT treatments may increase the risk of choroidal atrophy and neurosensory retinal degeneration.<sup>49,51</sup> The number of PDT treatments has also been shown to be inversely associated with visual acuity improvement; whether this is because larger tumors

are more likely to require more PDT treatments or if this reflects a side-effect of PDT treatment is unknown.<sup>37</sup> Recurrence of subretinal fluid following PDT has been reported, often many months or years later, with some patients requiring multiple treatments.<sup>54</sup>

LP, light perception; PDT, photodynamic therapy; RPE, retinal pigment epithelium;

TTT, transpupillary thermotherapy; VA, visual acuity.

## Laser Photocoagulation

Laser photocoagulation or “thermal laser” with xenon arc or argon laser was one of the earlier primary treatments of circumscribed choroidal hemangioma prior to the development of PDT.<sup>5</sup> In the Shields' series of 86 patients who were treated with argon laser photocoagulation, 62% of patients had complete resolution of subretinal fluid and 71% of patients had visual stability or improvement.<sup>5</sup> An earlier case series in 1989 by Anand et al., where 42 patients underwent treatment with argon or xenon laser, showed a 79.2% rate of initial visual acuity and subretinal fluid improvement, but a 40% rate of recurrent subretinal fluid after initial treatment.<sup>55</sup> All of the patients had resolution of subretinal fluid with retreatment at the end of the follow-up period.<sup>55</sup> Another series by Madreperla et al. describes 13 patients treated with laser photocoagulation where 38% had vision better than 6/12 and 46% had no subretinal fluid at 1 year.<sup>56</sup> However, laser photocoagulation cannot be used to treat subfoveal lesions and laser photocoagulation does not reduce tumor size, resulting in a higher rate of recurrent exudation.<sup>34</sup> A single report of successful treatment of choroidal hemangioma with grid photocoagulation has also been reported.<sup>57</sup> Patients who have failed laser photocoagulation treatment often require subsequent radiation treatment or PDT.

## Transpupillary Thermotherapy

As opposed to laser photocoagulation, transpupillary thermotherapy (TTT) utilizes relatively long-pulse and low-energy laser to raise the temperature within treated tumor tissue, causing heat-induced sclerosis of vascular channels and eventually tumor regression and resolution of subretinal fluid.<sup>58</sup> TTT technically differs from laser photocoagulation in that the goal is optimal heat penetration rather than coagulation, and has been used more successfully for treatment of choroidal tumors.<sup>59</sup> TTT is felt to be most appropriate for circumscribed choroidal hemangiomas with shallow subretinal fluid that are posterior to the equator, with a

tumor base <10 mm and tumor thickness <4 mm.<sup>58</sup> If the tumor is larger than these dimensions, or if there is extensive subretinal fluid, tumor visualization may be difficult and prevent accurate focusing of the laser beam.<sup>58</sup> TTT may not be ideal in cases where the tumor margin touches the optic disc given the risk of thermal papillitis, which was reported in two of 80 eyes having TTT for juxtapapillary choroidal melanoma.<sup>60</sup> The use of TTT for subfoveal tumors is likely suboptimal in many cases as TTT is not selective for abnormal or choroidal tissue and may have adverse effects on normal retina.<sup>58</sup>

Gunduz published a review in 2004 of 38 cases (10 cases managed by the author and 28 cases from the published literature) of circumscribed choroidal hemangioma primarily treated with TTT. He found that all tumors ceased leaking after TTT with resolution of subretinal fluid.<sup>58</sup> Of these, 42% of tumors showed complete regression, 53% demonstrated partial regression by at least 10%, and 5% showed no change in tumor thickness.<sup>58</sup> After excluding 12 patients whose pretreatment visual acuities were less than 20/400, visual acuity improved by two or more Snellen lines in 77% of eyes and remained unchanged in the remaining 23% of eyes.<sup>58</sup> Complications included branch retinal vein occlusion in one eye, cystoid macular edema in three eyes, preretinal fibrosis in two eyes, and focal iris atrophy in three eyes.<sup>58</sup> While all of the cases reviewed by Gunduz were <4 mm thick and <10 mm in tumor diameter, there has been one report by Rishi et al. of a large subfoveal circumscribed choroidal hemangioma 6 mm in height and 14 mm in diameter with near total exudative retinal detachment treated with TTT which showed resolution of subretinal fluid.<sup>58,61</sup> Visual acuity improved from light perception to 10/200 at 6 months.<sup>61</sup> There is also one report by Kamal et al. where indocyanine green dye was injected prior to TTT to enhance laser uptake.<sup>62</sup>

## Transscleral Diode Cyclophotocoagulation

A single report from Feng et al. has suggested favorable outcomes may be achieved with this modality for circumscribed choroidal hemangioma, although significant scarring and RPE changes

appear to result. The proposed benefit of transsceral diode cyclophotocoagulation is its significant reduced cost compared to PDT.<sup>63</sup>

## Radiotherapy

Choroidal hemangiomas are extremely radiosensitive. However, radiation treatment is typically reserved for patients with extensive retinal detachment, those who cannot be treated with or are refractory to treatment with thermal laser or PDT. Radiation therapy often results in retinal reattachment and tumor regression in these patients although this can be accompanied by radiation-induced side-effects such as cataract, radiation retinopathy, and optic neuropathy.<sup>64</sup> However, noting the generally lower dose needed to treat circumscribed choroidal hemangiomas, the risk of radiation complications is generally less than treating other choroidal tumors, including posterior uveal melanoma. Radiation has historically also been used in patients with subfoveal choroidal hemangiomas that were not amenable to laser photocoagulation, although this role has been supplanted by PDT.

### Conventional External Beam Radiotherapy

Lens-sparing conventional gamma-ray external beam radiotherapy has been used for the treatment of circumscribed choroidal hemangioma. The largest series was reported by Schilling et al. in 1997, in which 36 eyes were treated with a dose of 20 Gy.<sup>65</sup> A total of 63.8% of patients experienced resolution of subretinal fluid, and visual acuity was stable or improved in 78% of patients.<sup>65</sup> Four cases of subretinal fibrosis leading to decreased final visual acuity are reported, but no reports of radiation-induced side-effects such as radiation retinopathy or cataract were found over a mean follow-up period of 4.5 years.<sup>65</sup> Ritland et al. treated nine eyes with circumscribed choroidal hemangioma with 20–24 Gy resulting in resolution of subretinal fluid, stable or improved visual acuity, and tumor regression in all cases.<sup>66</sup> Over the mean follow-up time of 3.6 years, no radiation-induced side-effects were observed.<sup>66</sup> Shields et al. reported two patients treated with external beam radiotherapy, both of whom had stable or improved visual acuity.<sup>5</sup> Madreperla et

al. also reported two patients treated with lens-sparing external beam radiotherapy, one of whom had resolution of subretinal fluid.<sup>56</sup>

## **Plaque Brachytherapy**

Plaque brachytherapy with palladium-103, cobalt-60, ruthenium-106, and iodine-125 have all been reported for the treatment of circumscribed choroidal hemangioma.<sup>5,56,67-70</sup> Compared with external beam radiotherapy, plaque brachytherapy offers more localized delivery of radiation to the tumor itself, minimizing radiation-induced side-effects.<sup>67</sup> The disadvantages of plaque brachytherapy are the necessity of two surgeries for plaque placement and removal, as well as heterogeneous radiation dose to the tumor base and apex. Zografos et al. reported the largest series of 39 patients with circumscribed choroidal hemangioma treated with cobalt-60 plaque brachytherapy who had 100% retinal reattachment.<sup>70</sup> Complications included pigment migration into the treated area, subretinal fibrosis, and an areolar atrophic scar.<sup>70</sup> Shields et al. reported the second-largest series of 15 patients treated with plaque radiotherapy, all of whom had resolution of subretinal fluid and 53% of whom had stable or improved visual acuity.<sup>5</sup> Lopez-Caballero et al. also treated eight patients with iodine-125 plaque brachytherapy, all of whom experienced resolution of subretinal fluid and some decrease in tumor thickness and 75% of whom had stable visual acuity.<sup>69</sup> Three patients developed radiation retinopathy, and one patient developed subretinal fibrosis.<sup>70</sup> Madreperla et al. treated two patients with iodine-125 and six patients with ruthenium-106 plaque brachytherapy, all of whom had resolution of subretinal fluid and 75% of whom had final vision better than 6/12.<sup>56</sup> Aizman et al. treated five patients with palladium-103 plaque brachytherapy – all five patients had resolution of subretinal fluid with some degree of tumor regression and three patients had improvement in visual acuity.<sup>67</sup> Chao et al. also reported one case where iodine-125 plaque brachytherapy was used as an alternative to enucleation in a patient with no light perception vision, total retinal detachment, and iris neovascularization; the posttreatment visual acuity remained no light perception, but the retinal detachment and iris

neovascularization resolved.<sup>68</sup>

## **Stereotactic Radiotherapy**

Stereotactic radiotherapy is a form of external beam gamma-irradiation that uses multiple treatment angles to provide a more homogeneous dose of radiation to target tissues and reduce radiation-related effects on healthy tissues. "Stereotactic radiosurgery," "gamma knife," and "cyberknife" are terms used to describe different forms of stereotactic radiotherapy. Two different Korean groups have reported on the use of gamma knife radiotherapy for the treatment of choroidal hemangioma.<sup>71-73</sup> Kim et al. have reported on the use of the Leksell gamma knife for symptomatic choroidal hemangiomas in seven patients, three of whom had the circumscribed form.<sup>72</sup> In the three patients with circumscribed choroidal hemangioma treated with a marginal dose of 10 Gy, the exudative retinal detachment resolved completely within 3 months and visual acuity improved in all three cases.<sup>72</sup> Song et al. also published their results with gamma knife radiotherapy for choroidal hemangioma with exudative retinal detachment, two of which were circumscribed, and they found that the retinal detachment resolved in both cases; however, vision worsened in one patient and was stable in the other.<sup>71</sup> The marginal dose used in this series was 26.7 Gy.<sup>71</sup>

Kivela et al. have also published a series of five patients with perifoveolar and peripapillary circumscribed choroidal hemangiomas treated with 20 Gy of stereotactic radiotherapy.<sup>74</sup> Exudative retinal detachments resolved within 6 months in four eyes and within 20 months in the fifth eye, and visual acuity improved or remained stable in four of five eyes.<sup>74</sup>

## **Proton Beam Radiotherapy**

Proton beam radiotherapy is a nonstereotactic form of external beam radiotherapy and may have some advantages compared to traditional gamma rays. Most importantly, the "Bragg peak" phenomenon of protons may allow for a more tailored and homogenous area of treatment and less collateral radiation damage compared to external gamma-irradiation.<sup>75</sup> However, a disadvantage of protons compared to external beam gamma-

irradiation is that surgical placement of tantalum clips is required with the former to permit tumor localization during treatment.

The largest series, of 71 patients, treated with proton beam therapy was reported by Levy-Gabriel et al. in 2009.<sup>76</sup> After treatment with 20 cobalt gray equivalents (CGE), retinal reattachment was achieved in 100% of patients, tumor regression in 91.5% of patients, and visual acuity improved by two or more lines in 52%.<sup>76</sup> Complications included cataract in 28% of patients and radiation-induced maculopathy in 8%.<sup>76</sup> In 2004, Frau et al. reported a series of 17 patients with circumscribed choroidal hemangiomas with serous retinal detachments treated primarily with low-dose proton therapy at 20 CGE.<sup>64</sup> At 2-year follow-up, 94% of patients had visual acuity improvement of two or more lines and 65% of patients had complete tumor resolution.<sup>64</sup> In 2014, Zeisberg et al.<sup>75</sup> presented relatively long-term results (mean follow-up 55.4 months) from a series of 50 patients with circumscribed choroidal hemangioma also treated with proton beam radiotherapy at 20 CGE. In this series, radiotherapy was used as primary treatment in 82% of patients, the others having undergone previous photodynamic therapy. Visual improvement of 2 lines or more was achieved in 58.8% of patients, but 46% developed radiation-retinopathy after a mean of 14.5 months with some patients developing vitreous hemorrhage, dry eye, and radiation-induced optic neuropathy. Earlier series reported results with higher doses of radiation; Hannouche et al. reported a series of 13 patients with circumscribed choroidal hemangiomas with serous retinal detachments who underwent proton therapy at a total dose of 30 CGE.<sup>77</sup> All patients had resolution of subretinal fluid, and 62% had improvement of visual acuity by two or more lines.<sup>77</sup> Zografos et al. treated 48 eyes with circumscribed choroidal hemangioma, and all of the patients had resolution of exudative retinal detachment at last follow-up (6 months to 9 years).<sup>78</sup> The radiation dose ranged from 16.4 to 27.3 Gy, and the three patients treated with 27.3 Gy all developed optic neuropathy.<sup>78</sup> Finally, there is one recent report from Chan et al. where they used a nonsurgical light-field technique without surgical tumor localization at doses of 15–30 CGE with good results.<sup>79</sup>

## Intravitreal Pharmacologic Therapy

### Intravitreal Anti-VEGF Injection

A few cases of circumscribed choroidal hemangioma treated with intravitreal injection of bevacizumab have been reported.<sup>80–83</sup> Most patients in these series received intravitreal bevacizumab for persistent intra- or subretinal fluid following more established treatments such as PDT, TTT, or laser photocoagulation and showed variable responses. In a few cases, intravitreal bevacizumab was used as primary treatment for symptomatic circumscribed choroidal hemangioma without adjuvant. Mandal et al. describe one patient who achieved resolution of intraretinal and subretinal fluid with a series of two injections of intravitreal bevacizumab, but without visual improvement.<sup>81</sup> Kwon et al. present four patients who underwent primary treatment of circumscribed choroidal hemangioma with serous retinal detachment with one or two intravitreal injections of bevacizumab. Of these, three patients had persistent improvement in subretinal fluid, although follow-up was limited (mean 6 months). Kwon et al. reflect that although bevacizumab may be initially effective at reducing fluid, its treatment duration may be limited.<sup>83</sup> A case of choroidal hemangioma unresponsive to intravitreal ranibizumab has been reported.<sup>84</sup> In addition, one case of intravitreal ranibizumab being used to effectively treat choroidal neovascularization secondary to PDT of circumscribed choroidal hemangioma has also been reported.<sup>13</sup>

### Intravitreal Glucocorticoid Therapy

Minimal literature exists regarding the use of intravitreal glucocorticoids to treat circumscribed choroidal hemangioma. One report of intravitreal triamcinolone injection to successfully treat several patients with circumscribed choroidal hemangioma-associated neovascularization has been published, and repeat injections were required in most.<sup>85</sup> In addition, a more recent report regarding the successful use of combined PDT and intravitreal dexamethasone implant to treat subretinal fluid associated with circumscribed choroidal hemangioma has been published, although the patient was treatment-naïve and may have responded to PDT

alone.<sup>86</sup>

## Conclusions

Circumscribed choroidal hemangiomas are benign vascular hamartomas without systemic associations, which do not require systemic workup or treatment. For symptomatic lesions, PDT has emerged as the treatment of choice with high rates of tumor and subretinal fluid regression and minimal complications. For centers where PDT is not available, TTT or laser photocoagulation remain reasonable alternatives, although they are not recommended for subfoveal lesions. Radiation therapy is usually reserved for larger hemangiomas with extensive bullous retinal detachment and which are not amenable to PDT, TTT, or photocoagulation treatment as radiotherapy is more technically involved, may cause radiation-related complications, and/or may require travel to specialized centers. Limited data suggest that intravitreal bevacizumab may reduce exudation in some circumscribed choroidal hemangiomas and may be more effective in cases of recurrent exudation following previously successful ablative treatment, although the duration of any effect may be limited.

**Conclusion**

## **Introduction**

A great variety of primary tumors occur in the uvea. Of these, rare tumors are difficult to diagnose clinically because they often do not have enough characteristics that distinguish them from the more common tumors. However, knowledge of the epidemiologic factors, clinical features, and natural history of some of the rare tumors may allow the clinician to suspect them preoperatively. Because many of these tumors are benign, preoperative recognition could prevent or minimize surgical intervention. The more common of these overall rare tumors are covered in detail in this chapter, and their unique aspects are emphasized.

## **Epithelial Tumors of the Ciliary Body: Congenital**

## Medulloepithelioma

Medulloepithelioma (diktyoma, teratoneuroma) is a rare congenital tumor most commonly seen in children that is generally believed to arise from the epithelium of the medullary tube. This tumor usually arises from the ciliary body epithelium, but medulloepitheliomas of the retina and the optic nerve also occur. The first detailed histologic description of the tumor was by Verhoeff,<sup>1</sup> who called it a teratoneuroma, despite the absence of teratomatous features. Fuchs<sup>2</sup> reported his observations of a medulloepithelioma and coined the term diktyoma because of the netlike appearance of cells composing the tumor. Grinker<sup>3</sup> was the first to use the term “medulloepithelioma,” which has become the preferred name because it refers to the correct cell of origin.

Several large series of medulloepitheliomas have been reported<sup>4-7</sup> and provide the bulk of our knowledge of the clinical features of this tumor. In Broughton and Zimmerman's series,<sup>5</sup> the median age at occurrence of initial symptoms was 3.8 years, with a range of 6 months to 41 years. Andersen<sup>4</sup> reported that the average age at the time of enucleation was 4.5 years for benign medulloepitheliomas and 7 years for malignant tumors. In the series of Canning et al.<sup>6</sup> the median age at diagnosis was 3 years. In all three series, all tumors were unilateral and single, and there was no racial or hereditary predisposition. A more recent case series by Kaliki et al. described 41 cases with a median age at presentation of 5 years; 78% of cases occurred in the first decade of life.<sup>7</sup> This tumor is extremely rare in adults aged >20 years.

The signs and symptoms of the 56 patients reported on by Broughton and Zimmerman<sup>5</sup> are summarized in [Tables 158.1](#) and [158.2](#).

One remarkable feature of medulloepitheliomas is the frequent presence of cysts, which are formed by the production of mucopolysaccharide by the epithelial cells. These cysts can be present within the body of the tumor but also may be free-floating in the anterior or posterior chamber and vitreous (Figs. 158.1–158.4). The presence of vitreous or anterior chamber cysts should alert the clinician to consider the possibility of a diagnosis of medulloepithelioma, although vitreous cysts have also been described with malignant melanoma.<sup>8</sup>

**FIG. 158.1** External photograph showing ciliary body mass. (Case presented by Milton Boniuk, Verhoeff Society, 1997.)

**FIG. 158.2** Gross appearance of medulloepithelioma demonstrating ciliary body mass and cysts in the posterior chamber. (Case presented by Milton Boniuk, Verhoeff Society, 1997.)

**FIG. 158.3** Histopathology showing epithelial nature of the tumor with cysts formed by epithelium surrounding mucopolysaccharide-filled spaces (hematoxylin and eosin; ×100).

**FIG. 158.4** Histopathology demonstrating cystic spaces overlying ciliary body epithelium (hematoxylin and eosin; ×400).

Another noteworthy feature of medulloepithelioma is that the intraocular pressure is frequently elevated at the time of diagnosis (see [Table 158.2](#)). This may result from secondary angle closure by the ciliary body mass, iris neovascularization, or growth of tumor cells across the trabecular meshwork. Medulloepitheliomas also have an unusual tendency to produce a retrolental neoplastic cyclitic membrane, which extends from the tumor, and is speculated to represent tissue migration over the anterior hyaloid.<sup>7</sup>

Medulloepitheliomas usually contain, as their most significant component, sheets and cords of poorly differentiated neuroepithelial tissue. The cellular cords may line cystic spaces filled with acid mucopolysaccharide. Homer Wright and Flexner–Wintersteiner rosettes may be present, but more commonly the rosettes in medulloepithelioma are larger than those seen in retinoblastoma. Typically, the lumina of the rosettes are surrounded by multiple cell layers, which resemble primitive ciliary epithelium, rather than photoreceptors.

In addition to the neuroepithelial tissue, medulloepitheliomas may contain heteroplastic tissues, in which case they are called teratoid medulloepitheliomas. Hyaline cartilage, striated muscle, undifferentiated mesenchymal cells, and neurologic tissue resembling the brain have all been described in teratoid medulloepitheliomas.

Medulloepitheliomas may be benign or malignant. Broughton and Zimmerman<sup>5</sup> considered 66% of the tumors in their series to be malignant. Andersen,<sup>4</sup> using more stringent criteria, classified 26% of the tumors in his series as malignant. From a practical point of view, even cytologically benign medulloepitheliomas can be locally invasive, extending into the iris, cornea, sclera, or orbit. For that reason all medulloepitheliomas should be considered as potentially malignant tumors, as recommended by Andersen.<sup>4</sup>

The initial treatment in most cases has been surgical – iridectomy, iridocyclectomy, partial sclerouvectomy or enucleation – and with total excision, the prognosis is excellent. Treatment success with radiation therapy has also been reported.<sup>9,10</sup> Canning et al.<sup>6</sup> have stressed the importance of attempting local resection (i.e., iridocyclectomy) only in patients with very small tumors. Of the four patients in their series who were treated by iridocyclectomy,

all subsequently required enucleation. A total of 45 (80%) of the patients in Broughton and Zimmerman's series<sup>5</sup> treated by iridocyclectomy subsequently required enucleation.

In both Broughton and Zimmerman's<sup>5</sup> and Anderson's<sup>4</sup> series of patients, the most important prognostic factor for survival appeared to be extension of tumor into the orbit. In Broughton and Zimmerman's series,<sup>5</sup> 11 patients had extraocular extension; of this group, four died of tumor-related causes. Intracranial spread of tumor was the usual cause of death, although one patient died of lymphatic spread to the mediastinum. The effectiveness of exenteration, radiation therapy, or chemotherapy – used individually or in combination – in managing extraocular extension is not established at this time. Such methods should be considered in cases with extrascleral extension because of the high tumor-related morbidity and mortality in this group of patients.

## Glioneuroma

Glioneuromas are choristomatous malformations that arise from the medullary epithelium of the anterior portion of the optic cup. They are extremely rare, and only a few cases have been reported.<sup>11-15</sup>

Glioneuromas usually appear as a mass involving the peripheral iris and ciliary body and are usually evident within the first 6 months of life. The tumor may involve the choroid and the retina, and extraocular extension has been described. Associated ocular abnormalities are frequently present and have included persistent hyperplastic primary vitreous in the same or contralateral eye and coloboma of the iris and ciliary body. Progressive enlargement of the tumor may lead to corneal opacification, cataract, or glaucoma.

These tumors are composed of well-differentiated neural tissue, including neurons and astrocytes. All the reported cases<sup>11-15</sup> have eventually required enucleation because of complications of the enlarging tumor or suspected malignancy. Because this is a benign tumor, it could conceivably be managed by local resection.

## Astrocytoma

Only three cases of astrocytoma of the ciliary body have been

reported.<sup>16-18</sup> Patients were 24 years, 52 years, and 29 years old at presentation. All three had solid tumors of the ciliary body, and in one patient the astrocytoma was associated with neovascular glaucoma. These tumors may be choristomas of the anterior portion of the optic cup. Two consisted of pilocytic astrocytes and the other of fibrillary astrocytes. All tumors were treated by local resection. Interestingly, in the patient with neovascular glaucoma, the rubeosis was observed to diminish after removal of the tumor.

## **Epithelial Tumors of the Ciliary Body: Acquired**

### **Pseudoadenomatous Hyperplasia: Reactive**

Hyperplasia of the ciliary epithelium may occur as a nonspecific response to trauma or inflammation. The hyperplastic tissue is primarily composed of nonpigmented ciliary body epithelium but may contain pigmented ciliary epithelium and blood vessels. Rarely, reactive hyperplasia may result in a mass that could be confused with a ciliary body neoplasm. More commonly, the hyperplastic tissue forms in sheets or as a cyclitic membrane.

### **Senile Hyperplasia**

Senile hyperplasia (Fuchs adenoma) is a benign condition. These lesions are typically white in color and are located in the pars plicata. They consist of sheets and tubules of hyperplastic nonpigmented ciliary body epithelium, with alternating areas of material that is like basement membrane. The frequency with which Fuchs adenoma is seen increases with age, and this tumor may be observed in approximately 20% of postmortem eyes. These lesions are significant because, when noted through gonioscopy, cycloscopy, or ultrasonography, they may be confused with malignant lesions.<sup>19,20</sup> Fuchs adenomas can cause a sectoral cataract.<sup>19</sup> These lesions are almost always <2 mm in size, but rarely can grow larger. The authors recently performed iridocyclectomy

on a 52-year-old man for a pigmented ciliary body tumor of nearly 3 mm in thickness suspected to be a small melanoma, and found it was a Fuchs adenoma (unpublished observation). In unusual cases with diagnostic uncertainty and concern for melanoma, iridocyclectomy can be performed, but Fuchs adenomas require no treatment.

## Adenomas and Adenocarcinomas

Adenomas and adenocarcinomas have been described by various names, including benign and malignant epitheliomas and adult medulloepitheliomas.<sup>21</sup> Adenomas and adenocarcinomas of the ciliary epithelium appear as solid tumors of the ciliary body. In Andersen's review of 30 of these cases, the presenting symptom was an observed mass in nine cases and decreased visual acuity in eight cases.<sup>4</sup> Other manifestations included glaucoma, cataract, pain, and proptosis. The average age of the patients with adenomas at the time of enucleation was 43 years. For the patients with adenocarcinomas, the average age at the time of enucleation was 55 years. It is noteworthy that several of the reported adenocarcinomas were present in blind eyes involving a previous history of trauma, suggesting that the adenocarcinomas may have represented malignant transformation of reactive hyperplasia of the ciliary epithelium.

The pathologic basis of these tumors has been more thoroughly described elsewhere.<sup>7</sup> Briefly, the adenomas consist of cuboidal or columnar cells resembling the nonpigmented or pigmented ciliary epithelium. These cells may have a tubular or papillary arrangement and may be closely packed or enmeshed in a mucoid material.<sup>22</sup> The malignant lesions may be well differentiated, in which case they resemble the adenomas but have more cytologic features of malignancy. The poorly differentiated lesions are more pleomorphic and may resemble a metastatic adenocarcinoma or even a sarcoma.<sup>21,23</sup>

Because these lesions cannot be reliably differentiated from melanomas, they are usually treated by enucleation or brachytherapy. It is evident that extraocular extension is an important factor in prognosis.<sup>4,23</sup> Andersen reported two cases of

adenocarcinoma that had extended outside the globe at the time of enucleation.<sup>4</sup> Both of the patients developed intracranial extension of the tumor. Laver et al. reported on 12 cases of pleomorphic adenocarcinoma of the ciliary epithelium, nine of which occurred in phthisical eyes. Fatal cases occurred only in tumors with extraocular extension. They noted that clinically adenocarcinomas should be considered in adults who develop an epibulbar mass and/or proptosis in the setting of a long-standing blind eye.<sup>23</sup> The role of exenteration, radiation therapy, or chemotherapy in extraocular extension has not been defined.

## Melanocytic Tumors

### Melanocytoma

The term melanocytoma was first used by Zimmerman and Garron<sup>24</sup> to describe a benign pigmented tumor of the optic nerve. Other names that have been used to designate this same lesion include magnocellular nevus and benign melanoma.

Melanocytomas of the optic nerve and peripapillary choroid are described in [Chapter 140](#) (Congenital hypertrophy of the retinal pigment epithelium). Therefore only melanocytomas limited to the uvea are discussed here.

Uveal melanocytomas appear as very darkly pigmented tumors of the choroid, ciliary body, or iris ([Fig. 158.5](#)). Although they are probably congenital lesions, the age range at the time of presentation is not sufficiently different from that of malignant melanomas to be useful in differential diagnosis. In a review of ciliary body melanocytomas, Frangieh et al.<sup>25</sup> found that most of the reported cases have been in Caucasians. Therefore, unlike optic nerve melanocytomas, uveal melanocytomas do not occur predominantly in pigmented individuals. Distinguishing this benign tumor from malignant melanoma is further complicated by the ability of melanocytomas to undergo slow growth. Such slow growth may result in extension of the tumor through the sclera to the episclera. Also, melanocytomas may undergo necrosis, resulting in pigment dispersion, uveitis, and melanomalytic glaucoma.<sup>26</sup> Kathil et al. have described the clinical features of anterior uveal

melanocytomas that may be useful in distinguishing melanocytomas in the anterior segment from melanoma.<sup>27</sup>

**FIG. 158.5** Fundus photograph showing a choroidal melanocytoma.

Melanocytomas are composed of plump, polyhedral, densely pigmented cells, with small eccentrically placed nuclei that lack prominent nucleoli (Figs. 158.6 and 158.7). These cells are indistinguishable from the plump, polyhedral cells described by Naumann et al.<sup>28</sup> as the exclusive component in approximately 10% of choroidal nevi. Evidence that malignant melanomas may develop from uveal melanocytomas has been provided by cases in which melanomas were present and adjacent to lesions that were indistinguishable from melanocytomas.<sup>29-31</sup>

**FIG. 158.6** Melanocytoma: the cells are characteristically darkly pigmented (hematoxylin and eosin;  $\times 400$ ).

**FIG. 158.7** Bleached sections demonstrate the bland peripherally located nucleus typical of melanocytoma (bleached sections;  $\times 400$ ).

Melanocytomas require no treatment, except for secondary complications. Because these tumors may have the potential for malignant transformation, they should be followed to document changes suggestive of malignancy. Ultrasound biomicroscopy can often be helpful in this setting. However, it may be impossible, on the basis of noninvasive studies, to differentiate melanomas from

enlarging melanocytomas, so some melanocytomas inevitably will be treated surgically.

## **Bilateral Diffuse Uveal Melanocytic Proliferation (BDUMP) Associated With Systemic Malignant Neoplasms**

In 1982 Barr et al.<sup>32</sup> described a syndrome characterized by bilateral diffuse melanocytic tumors of the uvea in patients with nonocular malignancy. This condition was originally reported by Machemer<sup>33</sup> and has been recently reviewed by Satio et al.<sup>34</sup> Gass et al.<sup>35</sup> summarized the clinical features of this syndrome, which are (1) multiple, round or oval, red-to-brown patches at the level of the retinal pigment epithelium in the posterior fundus; (2) a striking fluorescein angiographic pattern of early hyperfluorescence corresponding with these patches; (3) development of multiple, elevated, variably pigmented uveal melanocytic tumors and diffuse thickening of the uveal tract; (4) exudative retinal detachment; and (5) rapid progression of cataract.

Patients with this syndrome have had various nonocular malignancies, including adenocarcinomas of the gallbladder, ovary, colon, or pancreas, and squamous cell carcinoma of the lung and cervix. Most patients with this syndrome have died within 12–24 months after diagnosis, but long-term survival has been reported.

Histopathologic study of the uvea in patients with this syndrome has disclosed uveal melanocytic tumors. The cytologic features of the tumors are variable, with most of the cells having benign cytologic features. However, cytologic features of malignancy have been present in several cases,<sup>32,36</sup> although no metastatic disease has been documented. Recently, Miles et al. have shown that the serum from patients with BDUMP contains a factor that promotes melanocyte proliferation, suggesting this may be the etiology of the benign melanocytic proliferation that is the hallmark of this condition.<sup>37</sup>

## **Neurogenic Tumors**

## Schwannomas (Neurilemmomas)

Choroidal and ciliary body schwannomas are rare benign tumors that can be mistaken for amelanotic uveal melanomas.<sup>38-40</sup> The majority of these tumors arise as an isolated condition, but may be associated with multisystem disorders, such as neurofibromatosis and the Carney complex.<sup>40</sup> The clinical presentation of these tumors is that of a solid ciliary body or choroidal tumor. Although cytologically benign, they may progressively enlarge at a rate similar to, or greater than, that of choroidal melanomas. In the case studied by Shields et al.,<sup>38</sup> preoperative ultrasound demonstrated acoustic hollowness, choroidal excavation, and low internal reflectivity. These findings are identical to those of choroidal melanoma. In two subsequently reported cases of anterior uveal schwannomas, the tumors were noted to transilluminate brightly.<sup>41,42</sup> This may be a helpful clinical finding because it is unusual for anterior uveal melanomas to transilluminate in this way. With increased suspicion, fine-needle biopsy and local resection may be considered.

Schwannomas arise from ciliary nerves in the uvea and are encapsulated tumors consisting of a pure proliferation of Schwann cells. The cells in these tumors are characteristically arranged as either solid sheets of cells (Antoni A pattern) or stellate-to-ovoid cells in a mucinous background (Antoni B pattern).

Because these tumors are cytologically benign, they require treatment only to prevent visual loss resulting from their progressive enlargement. Unfortunately, as with many primary uveal tumors, it is difficult to distinguish schwannomas from amelanotic malignant melanomas.

In the case reported by Shields et al.,<sup>38</sup> there was no clinical or histologic evidence that the tumor was responsive to radiation therapy. Damato et al. advocate diagnostic biopsy for smooth, amelanotic tumors, with local resection as the treatment of choice for confirmed cases of schwannoma. Photodynamic therapy may be an option for unresectable lesions.<sup>40</sup>

## Neurofibroma

Unlike schwannomas, uveal neurofibromas are highly associated

with neurofibromatosis. Choroidal neurofibromas are diffuse lesions and appear as diffuse thickening of the choroid, sometimes with an overlying sensory retinal detachment.<sup>43</sup>

Neurofibromas are nonencapsulated lesions composed of Schwann cells, axons, and fibroblasts. An increase in the number of dendritic uveal melanocytes may be present, simulating congenital melanosis oculi. No treatment is required except to manage vision-threatening complications. (Additional material on neurofibromas may be found in [Chapter 138](#), Remote effects of cancer on the retina.)

## Granular Cell Tumor

The cell type from which granular cell tumors originate is not definitely known; these tumors have features suggestive of a myogenic or neuroectodermal origin. A single case of granular cell tumor, involving the iris and ciliary body of a 24-year-old woman, has been reported.<sup>44</sup> The tumor was partially excised, but 1 year after treatment no enlargement of the remaining tumor was reported. Other cases of intraocular granular cell tumor have not been reported.

## Myogenic Tumors

### Leiomyoma

Leiomyomas are rare intraocular tumors that appear as a solid mass of the ciliary body or, less commonly, the choroid ([Fig. 158.8](#)). As with other solid tumors in these locations, they may cause secondary cataract, glaucoma, and retinal detachment. These tumors arise in younger patients and demonstrate a predilection for women.<sup>45</sup> Leiomyomas arise from the smooth muscle of the ciliary body. In the choroid they probably arise from the smooth muscle or pericytes of the choroidal vessels. They are composed of densely packed, nonpigmented, spindle-shaped cells with oval nuclei ([Fig. 158.9](#)). This histologic feature correlates with the very low internal reflectivity seen on A-scan echography of these lesions ([Fig. 158.10](#)). It is difficult to differentiate these tumors from amelanotic spindle

melanomas solely on the basis of light microscopic features. Immunohistochemical stains and ultrastructural evaluation (Fig. 158.10) are essential in making this distinction.

**FIG. 158.8** Clinical photograph of ciliary body leiomyoma.

**FIG. 158.9** Leiomyoma: the tumor is composed of typical smooth muscle cells with indistinct cell borders and spindle-shaped nuclei (hematoxylin and eosin;  $\times 400$ ).

**FIG. 158.10** A-scan echography reveals very low reflectivity of the tumor.

Clinically, it is very difficult to differentiate leiomyomas from malignant melanomas. As a result, leiomyomas are usually clinically diagnosed and treated as malignant melanomas. The Shields group has noted that leiomyomas of the ciliary body demonstrate increased transillumination, similar to schwannomas.<sup>46</sup> This feature may allow clinical distinction of this tumor from ciliary body melanomas, which generally do not transilluminate in this way. If the diagnosis is established clinically (e.g., by fine-needle biopsy), treatment should consist of managing the secondary complications of this benign tumor.

## Mesectodermal Leiomyoma

Mesectodermal leiomyoma has been used to describe a benign tumor of the ciliary body that has histologic and ultrastructural features of both smooth muscle and neural tissue (Fig. 158.11).<sup>46-48</sup> The peculiar combination of features in this tumor may be explained by the embryologic origin of the ciliary body smooth muscle from the neural crest. The designation mesectodermal leiomyoma should be reserved for tumors that have light or electron microscopic evidence of neurogenic tumors.

**FIG. 158.11** Transmission electron microscopy reveals the Z bands typical of smooth muscle.

## Miscellaneous

### Reactive Lymphoid Hyperplasia and Lymphoma

Lymphocytic tumors may involve the eye in myriad ways. Reactive lymphoid hyperplasia and lymphoma may both present as choroidal tumors (Figs. 158.12 and 158.13). Choroidal tumors due to lymphocytic infiltration tend to have a more irregular contour to the base of the tumor and often extend in a more circumferential fashion than is typical of melanocytic or neurogenic tumors of the choroid. In some cases there will be simultaneous involvement of the orbit or ocular adnexa. Lymphocytic tumors presenting in this fashion can represent isolated extranodal lymphoma (primary uveal lymphoma) or may be present in association with lymphoma at other sites (secondary lymphoma). Enhanced-depth optical coherence tomography can be helpful in diagnosis, with choroidal lymphoma demonstrating a characteristic “placid, rippled, or seasick” surface, correlating with increasing tumor thickness.<sup>49</sup> Definitive diagnosis requires incisional biopsy (Fig. 158.14), but may not be necessary if systemic workup reveals extraocular involvement that can be more easily biopsied to establish a diagnosis of systemic lymphoma. Patients with lymphoma should

undergo staging and treatment appropriate to the type and extent of lymphoma.

**FIG. 158.12** Uveal lymphoma: peripheral choroidal mass with the clinical appearance of choroidal detachment.

**FIG. 158.13** B-scan echography reveals the solid nature of the tumor.

**FIG. 158.14** Ciliary body biopsy reveals a diffuse infiltrate of mature-appearing small lymphocytes (hematoxylin and eosin;  $\times 200$ ).

## Juvenile Xanthogranuloma

Juvenile xanthogranuloma is a benign cutaneous disorder that typically affects young children. Zimmerman described the characteristic features of eye involvement associated with juvenile xanthogranuloma as (1) an asymptomatic localized or diffuse iris tumor, (2) unilateral glaucoma, (3) spontaneous hyphema, (4) a red eye with signs of uveitis, or (5) congenital or acquired heterochromia iridis.<sup>50</sup> The iris and ciliary body are most commonly the sites of intraocular involvement with this condition, but there have been case reports describing prominent involvement of the choroid, retina, and optic nerve.<sup>51,52</sup>

## Langerhans Cell Histiocytosis

Rarely, Langerhans cell histiocytosis<sup>53</sup> may present as a choroidal mass lesion without other orbital or systemic involvement.<sup>54</sup>

Langerhans cell histiocytosis occurs as the result of a clonal expansion of Langerhans cells. This monocytic cell type is an antigen-presenting cell, and it is unclear why a clonal expansion of this cell type might occur in the choroid. Involvement of the orbit, bones, or lungs is much more common.

## Hemangiopericytoma

Uveal hemangiopericytoma is an extremely rare neoplasm.<sup>55-57</sup> The clinical features of these tumors are similar to those of uveal melanomas, including the frequent presence of a sentinel vessel in cases of ciliary body hemangiopericytomas. In one of the reported cases of hemangiopericytoma the magnetic resonance signal characteristics of the tumor were different from those of choroidal melanomas.<sup>19</sup> The authors suggested that magnetic resonance imaging may provide a mechanism for distinction of this rare tumor from uveal melanoma.

Hemangiopericytomas may be benign or malignant. Complete surgical resection is the treatment of choice in either case.

## Rhabdomyosarcoma

A remarkable case of rhabdomyosarcoma of the ciliary body in a 12-year-old boy has been reported.<sup>58</sup> It is possible that this case represents the one-sided or complete differentiation of a teratoid medulloepithelioma along the line of a rhabdomyosarcoma. At the last reported follow-up examination (2 years after enucleation), the child was alive without evidence of metastasis or local recurrence. Three additional cases of primary rhabdomyosarcoma of the iris have been reported.<sup>58-61</sup>

## The Role of Diagnostic Biopsy for Uveal Tumors

Given the variety of rare lesions that occur in the uvea, often masquerading as more common clinical entities, it is useful to consider when a biopsy might be helpful diagnostically. The techniques and indications for biopsy have been reported by Lim et al.<sup>62</sup> Briefly, biopsy might be considered in anterior uveal tumors, particularly if they fail to block transillumination. Patients with current or past history of systemic diseases that are associated with choroidal tumors should also be considered for biopsy. Atypical amelanotic choroidal lesions can also be considered for diagnostic biopsy. Ciliary body and/or choroidal biopsy may be performed from an external approach, and choroidal lesions may also be biopsied using vitrectomy techniques. Fine-needle aspiration biopsies are sufficient for diagnosis in many cases, but incisional biopsy may be required. Such biopsies can generally be obtained with minimal morbidity. In a child, retinoblastoma must be eliminated as a diagnostic possibility prior to biopsy of an intraocular mass due to risk of orbital seeding of tumor. In adults, fine-needle aspiration biopsy is now commonly practiced and in cases of uveal melanoma associated with a very low risk of orbital spread of disease, but it is best performed by experts in intraocular tumor care.<sup>63</sup>

## Conclusion

A great variety of lesions, both benign and malignant, may appear as tumors of the ciliary body and choroid. It is often difficult to distinguish benign from malignant tumors clinically, but documentation of growth may prevent unnecessary treatment of some of the benign tumors such as Fuchs adenoma and astrocytoma. Knowledge of associated ocular and systemic conditions is also helpful in the recognition of some of these tumors, including medulloepithelioma, glioneuroma, reactive pseudoadenomatous hyperplasia, and neurofibroma. Nonetheless, many of these rare tumors do not have adequate epidemiologic or clinical characteristics to allow preoperative distinction from malignant melanomas. The safety and efficacy of fine-needle biopsy as an aid in differential diagnosis has been established in recent years and may allow characterization of some tumors before

definitive treatment is planned.<sup>64–67</sup>

## Introduction

Leukemias and lymphomas are myeloproliferative disorders that may affect the eye. Occasionally, the ophthalmic symptoms and findings can be the initial manifestation of the systemic illness.<sup>1,2</sup>

Estimates of the frequency of intraocular involvement with leukemia range as high as 90% of cases.<sup>1,3</sup> Although melanoma is the most common primary intraocular tumor in adults and retinoblastoma is the most common primary intraocular tumor in children, when secondary or metastatic neoplastic intraocular disease is considered, intraocular manifestations of hematologic malignancies are found to be overwhelmingly more common since the prevalence of myeloproliferative disorders is higher in the general population.

Liebreich first described leukemic retinopathy in the 1860s. Since that time, reports have documented that virtually all intraocular structures may be involved. Patients have been reported with leukemic infiltrates of the optic nerve, choroid, retina, iris, ciliary body, and anterior chamber. In addition, leukemic involvement may present as a serous retinal detachment.<sup>4</sup> A child with a leukemic hypopyon is illustrated in [Fig. 159.1](#). Central serous chorioretinopathy overlying areas of choroidal infiltration has been reported, as has retinal vascular sheathing, subconjunctival

hemorrhage, anterior chamber hemorrhage, intraretinal hemorrhage, and intravitreal hemorrhage.<sup>5</sup> Retinal changes may be related to direct invasion of tissue by neoplastic cells; to manifestations of associated hematologic abnormalities such as anemia, thrombocytopenia, or hyperviscosity states; to opportunistic infections; or to unrelated chance findings.

**FIG. 159.1** Leukemic iris infiltration in a child with acute lymphocytic leukemia. Note hypopyon inferiorly.

Intraocular infiltrates appear to correlate with associated central nervous system (CNS) involvement and decreased survival. The intraocular manifestations of leukemia are protean, and clinically, it usually is not possible to differentiate the various leukemias and lymphomas on the sole basis of their ophthalmoscopic findings.<sup>6</sup>

## Systemic Classification of Leukemia and Lymphoma

In general, the leukemias and lymphomas can be classified according to their cell of origin. Some examples of the neoplasias of B-cell origin include chronic lymphocytic leukemia, small-cell (well-differentiated) lymphocytic lymphoma, Burkitt lymphoma, and acute lymphocytic leukemia. Neoplasias that appear to have T-cell origin include chronic lymphocytic leukemia, mycosis fungoides, T-

cell leukemia, and angiocentric lymphoma. Reticulum cell- or histiocytic-derived neoplasias include malignant histiocytosis, the various monocytic leukemias, and Hodgkin disease.

At presentation, the acute leukemias most often have systemic manifestations of anemia, hemorrhage, infection, or signs and symptoms related to infiltration of organs. Acute lymphocytic leukemia is the predominant leukemia type in children, and more than 50% of these patients can be cured. In adults, acute myelogenous leukemia is the predominant myeloproliferative disorder, and survival rates are lower in adults than children.<sup>1</sup>

The chronic leukemias often first appear in an indolent manner. Symptoms may be vague. These diseases generally are found in older individuals. Although associated infections or other complications are often treated aggressively, many patients receive no treatment for their underlying disease because treatment has not definitely been shown to prolong survival. Some chronic leukemias degenerate into a “blast” (acute) phase, in which case the signs and symptoms resemble those of the acute leukemias.<sup>1</sup>

The lymphomas often initially appear with symptoms related to lymph node involvement. Signs and symptoms of bleeding diatheses and organomegaly are common. Additional information on the systemic aspects of the lymphomas is included later in this chapter.

## Leukemia

### Prevalence and Incidence

Limited data are available from prospective series of patients concerning ocular findings at the time of diagnosis.<sup>7-9</sup> Most clinical series contain cross-sections of patients seen both early and late during the course of the illness. Autopsy series, which presumably show the highest prevalence rates, often overstate the frequency with which clinical disease is detected.

Four autopsy series have shown variable prevalence data. Allen and Straatsma<sup>6</sup> found that 38 of 76 patients (50%) had ocular involvement by neoplastic disease or pathologic changes that could be directly ascribed to the neoplastic disease. Nelson et al.<sup>10</sup> found

that 33 of 117 patients (28%) with various types of leukemia had ocular metastases at the time of death. Leonardy et al.<sup>11</sup> found leukemic infiltrates in the eyes of 42 of 135 patients (31.1%), with the choroid being the most frequently involved site. Data from Kincaid and Green<sup>1</sup> are summarized in Table 159.1, which shows that 75% of patients with chronic leukemias, 82% of patients with acute leukemias, and 80% of affected patients in this study had intraocular involvement at the time of death.

Data from Kincaid MC, Green WR. Ocular and orbital involvement in leukemia. *Surv Ophthalmol* 1983;27:211–32.

Clinical series show highly variable prevalence rates. A small prospective series was reported by Karesh et al.,<sup>7</sup> who examined the fundus findings in 56 newly diagnosed, untreated patients with acute myelogenous leukemia. They found retinopathy at the time of initial examination in 28 of 56 patients (50%) and no cases of leukemic infiltration. Schachat et al.<sup>8</sup> reported on the largest series of patients with newly diagnosed leukemia examined within a few days of diagnosis. Among the 120 patients examined (65 with acute myelogenous leukemia, 51 with acute lymphocytic leukemia, and four with other leukemias), 62% had ocular abnormalities due to their underlying myeloproliferative disorder. In addition, Reddy and colleagues conducted a study examining 127 patients with acute leukemia within 2 days of diagnosis before starting chemotherapy, and these investigators found retinal lesions in 49% of cases.<sup>9</sup>

## Clinical Manifestations

The ocular manifestations of leukemia can be divided into direct manifestations (leukemic infiltrates), possible direct manifestations (e.g., white-centered retinal hemorrhages), manifestations of complications of leukemia (chiefly anemia, thrombocytopenia, and hyperviscosity states), opportunistic infections, and those related to medical therapy.

Reddy et al. reported on 127 individuals examined after diagnosis of acute leukemia and before initiation of chemotherapy. Abnormal retinal findings were noted in nearly half of all patients examined.<sup>9</sup> The most common retinal lesions were intraretinal hemorrhages (42%). Reddy and colleagues also reported on the ocular findings in 288 newly diagnosed cases of leukemia in adults and children. Clinical symptoms were present in 10%, but ocular findings were noted in 35.4%. Ocular findings were more common in adults (49%) than in children (16%) and were more frequent in myeloid leukemia (41%) compared with lymphoid leukemia (29.2%).<sup>12</sup>

Russo et al. evaluated 180 pediatric patients with acute leukemia and found ocular manifestations in 66% of children with acute myeloid leukemia and 11.5% of children with acute lymphocytic leukemia.<sup>13</sup> Data from multiple reports suggest the need for routine ocular examination of all patients with newly diagnosed acute leukemia regardless of whether they are symptomatic or not. Other investigators have also noted that chronic lymphocytic leukemia appears to have a very low prevalence of ocular involvement and routine screening of these patients at the time of diagnosis does not appear to be necessary.<sup>14</sup>

In our series of 120 cases examined at the time of diagnosis, four patients (3%) had leukemic infiltrates. In addition, intraretinal hemorrhages were present in 29 cases (24%), white-centered retinal hemorrhages in 13 cases (11%), vitreous hemorrhage in three cases (2%), and cotton-wool spots in 19 cases (16%). Miscellaneous findings, presumably unrelated to leukemia, were present in 20% of cases.<sup>8</sup> The low prevalence of leukemic infiltrates in our series differs from those reported in autopsy series. One potential reason for the lower prevalence is the ability to detect leukemic choroidal infiltrates, which are a frequent finding in autopsy series but are

difficult to diagnose clinically.

## Leukemic Infiltrates

### Retinal or Preretinal Infiltrates

Leukemic infiltrates have been described by several investigators. Kuwabara and Aiello<sup>15</sup> reported on a patient with chronic myelogenous leukemia with large gray-white nodules of varying sizes in the retina.<sup>15</sup> They suggested that this finding was an ominous prognostic sign and, in general, associated with high blood counts, fulminant disease, and early demise.<sup>16</sup> Merle and colleagues have described a subretinal infiltrate with venous vasculitis in a patient with adult T-cell leukemia.<sup>17</sup> As the ocular lesions progressed, the general health of the patient declined despite treatment with chemotherapy. Another patient with leukemic infiltrates is illustrated in Fig. 159.2. This type of pathologic change in the fundus was seen in 2–3% of patients in our prospective series.<sup>8</sup> Optic nerve infiltration may be the initial ocular manifestation of acute leukemia and can result in severe vision loss if not treated.<sup>18</sup> In addition, recurrent systemic lymphoma may also present with ocular infiltration, and diagnostic vitrectomy may be helpful in establishing the presence of active disease.<sup>19</sup>

**FIG. 159.2** (A,B) Right fundus photographs of a 19-year-old man with leukemic retinopathy and extensive midperipheral intraretinal and preretinal leukemic infiltrates with acute myelogenous leukemia. The patient died within 72 hours of presentation. (Courtesy of

Gray-white streaks along vessels may be caused by local perivascular leukemic infiltrates. A case of diffuse unilateral retinal angiopathy resembling frosted-branch angiitis that responded to local radiation and intrathecal chemotherapy was reported by Kim et al.<sup>20</sup> This case represented the sole manifestation of relapsing acute lymphoblastic leukemia in an 18-year-old man and also involved optic nerve infiltration in the same eye.

## **Choroidal Infiltrates**

Leukemia may also infiltrate the choroid; however, clinical signs of choroidal involvement are often subtle unless overlying retinal or retinal pigment epithelial (RPE) changes bring them to attention. Serous retinal detachment overlying choroidal infiltrates<sup>21</sup> or overlying frank choroidal masses<sup>22</sup> is an important clue. Histopathologic confirmation of choroidal infiltration has been reported in a patient with adult T-cell leukemia.<sup>23</sup>

Kincaid et al.<sup>24</sup> reported on a 71-year-old woman with an exudative retinal detachment, shifting subretinal fluid, and areas of diffuse pin-point fluorescein hyperfluorescence with dye leakage into the subretinal space. The patient had a poorly characterized and unusual leukemia. Histopathologic study showed that the choroid was moderately distended by a diffuse cellular infiltrate with an overlying serous retinal detachment. The RPE showed areas of depigmentation and proliferation. There were a few small areas of associated pigment epithelial detachment.<sup>24</sup> Gass<sup>25</sup> described a patient with myelomonocytic leukemia who had a discrete choroidal mass with an overlying serous retinal detachment. Pin-point hyperfluorescence was seen on the angiogram in areas overlying the mass (Fig. 159.3).

**FIG. 159.3** (A) Serous macular detachment in a 59-year-old white woman with leukemia. A small amount of blood (*solid black arrow*) is present. (B,C) Multiple, small pinpoint areas of leakage from the area of presumed choroidal infiltration. (Reproduced with permission from Gass JDM. *Stereoscopic atlas of macular diseases: diagnosis and treatment*. 4th ed. St. Louis: Mosby; 1997.)

Burns et al.<sup>26</sup> reported on a 37-year-old patient with acute lymphocytic leukemia who appeared to have “bilateral macular edema.” The patient was treated with ocular radiation on the assumption that underlying leukemic infiltration of the choroid was present, and this was confirmed at autopsy. Serous retinal detachment overlying areas of choroidal infiltration has been reported in patients with chronic lymphocytic leukemia, acute lymphocytic leukemia, chronic myelogenous leukemia, and acute myelogenous leukemia.<sup>1,27</sup> Serous RPE detachment has also been reported in a patient with acute lymphoblastic leukemia.<sup>28</sup> Exudative retinal and RPE detachments can be the presenting manifestation of the leukemia.<sup>29</sup> Eventually, as the fluid and detachment resolve, coarse clumping of the RPE is seen.<sup>21,28</sup>

Prominent pigment epithelial changes also may be seen after resolution of what may be retinal infiltrates. Jakobiec and Behrens<sup>30</sup> reported on a 3-year-old patient with acute leukemia who was found to have preretinal hemorrhages, some with white centers. A multitude of jet-black spots were seen, most prominently in the posterior pole. Soft white patches were described in the retinal periphery. The authors believed that these patches were the precursor lesions of the black spots. They postulated that the spots represented proliferation of pigment epithelial cells or small pigment epithelial detachments.<sup>30</sup> Clayman et al.<sup>21</sup> reported on a

child with acute lymphocytic leukemia who had massive pigmentary changes simulating leopard spots, most marked in the posterior pole (Fig. 159.4). At autopsy, the retina and the choroid were infiltrated with atypical immature lymphocytes. Areas of RPE hyperplasia were present, including heaped-up masses of pigment epithelium surrounding leukemic cells.

**FIG. 159.4** (A) Fundus photograph showing marked clumping of retinal pigment epithelium (RPE). (B) Heaped-up masses of RPE surrounding eosinophilic material and leukemic cells. (C) Higher magnification of an adjacent area showing a nodule of pigment epithelium and infiltration of the choroid and retina with leukemic cells. (Panels A and B courtesy of John T. Flynn; panel C reproduced with permission from Clayman HM, Flynn JT, Koch K, et al. Retinal pigment epithelial abnormalities in leukemic disease. *Am J Ophthalmol* 1972;74:416–9.)

## Vitreous Infiltrates

Vitreous opacities may be manifestations of an intraocular malignancy. Moribund patients may show massive collections of tumor cells in the vitreous, but most patients with intravitreal hemorrhage have neoplastic cells in the vitreous only because their peripheral blood contains tumor cells (Fig. 159.5). The cells do not

appear to be preferentially replicating in the vitreous cavity. Swartz and Schumann<sup>5</sup> described a patient with acute lymphocytic leukemia who had a dense vitreous cellular infiltration. Diagnostic vitreous aspiration confirmed the neoplastic nature of the process. Examination of the cerebrospinal fluid was also positive for blast cells. At the time, the peripheral blood was negative for tumor. The patient was treated with systemic and intrathecal chemotherapy and 1200 cGy of cranial radiation therapy. The vitreous cleared after the treatment.<sup>5</sup>

**FIG. 159.5** Leukemic patient with thrombocytopenia and combined subarachnoid and vitreous hemorrhage (Terson syndrome). Because the patient has a high peripheral blast count, it is certain that leukemic cells are present in the vitreous blood.

Belmont et al.<sup>31</sup> reported on a 72-year-old patient with chronic unilateral uveitis. Leukemic cells were found in the iris and throughout the vitreous at the time of a pars plana vitrectomy performed to rule out reticulum cell sarcoma. Isolated ocular blast crisis with leukemic hypopyon has been reported to occur in chronic myelogenous leukemia.<sup>32</sup> Vitreous cells and leukemic retinopathy have been reported in a single case of hairy cell leukemia (which constitutes less than 2% of adult leukemias).<sup>33</sup> A masquerade syndrome with primarily ocular findings of panuveitis in a patient with T-cell prolymphocytic leukemia was reported by Dhar-Munshi et al.<sup>34</sup> Additional cases of vitreous involvement in leukemia have been cited by Kincaid and Green,<sup>1</sup> as well as by Rothova et al.<sup>35</sup> Leukemic cells have been found in the vitreous of

patients with neovascularization of the disc. Delaney and Kinsella<sup>36</sup> reported on a patient with chronic myelogenous leukemia and disc neovascularization who had good peripheral perfusion, although the macula did show areas of nonperfusion. de Juan et al.<sup>37</sup> described a 3-year-old patient with acute lymphocytic leukemia who had disc neovascularization, vitreous hemorrhage, and vitreous infiltration. This case was unusual because neither the cell count nor the platelet count was remarkably elevated.

Hattenhauer and Pach<sup>38</sup> reported a single case of ocular B-cell lymphoma occurring in a patient with chronic lymphocytic leukemia. The occurrence of diffuse large cell lymphoma in patients with chronic lymphocytic leukemia is known as Richter syndrome. Richter syndrome is estimated to occur in 3–10% of patients with chronic lymphocytic leukemia. It portends an abrupt deterioration in health and carries a poor prognosis for survival.

Vitreous involvement also has been seen at the time of autopsy in patients with reticulum cell sarcoma, Burkitt lymphoma, multiple myeloma, and Hodgkin disease (discussed later in the chapter).

## **Possible Leukemic Infiltrates**

Duane et al.<sup>39</sup> reviewed the causes of white-centered retinal hemorrhages (Fig. 159.6) and also described possible pathophysiologic mechanisms. The authors suggested that these lesions should be classified as suspicious for direct intraocular manifestations of leukemia, since aggregates of leukocytes have been reported in the center of white-centered hemorrhages.<sup>40,41</sup> However, it should be noted that white-centered retinal hemorrhages can be composed of fibrin-platelet aggregates and are not necessarily a definite sign of neoplasia.

**FIG. 159.6** White-centered retinal hemorrhage visible above the center of the macula. The patient has acute lymphocytic leukemia.

## Manifestations of Anemia and Thrombocytopenia

Leukemic retinopathy is the term most often used to denote the fundus manifestations of anemia, thrombocytopenia, and increased blood viscosity seen in patients with leukemia. In general, the term does not necessarily refer to frank leukemic proliferation. The changes of “leukemic retinopathy” may be more commonly seen with the acute leukemias, but the frequency with which they occur has not been adequately studied to be certain. Although perivascular sheathing may be due to actual perivascular infiltrates, tortuous dilation of the retinal veins probably is not. The veins and arteries may assume a yellowish tinge because of both anemia and leukocytosis.<sup>1</sup> Retinal hemorrhages may occur, often at the posterior pole, and may be subretinal, deep retinal, superficial retinal, or preretinal, with potential breakthrough bleeding into the vitreous cavity. Hemorrhages may have a blot or blotch shape, flame shape, or they may have white centers (Figs. 159.7 and 159.8).<sup>39</sup>

**FIG. 159.7** Leukemic retinopathy with cotton-wool spots, nerve fiber layer hemorrhages, and hemorrhages in deep retinal layers. The patient has acute myelogenous leukemia.

**FIG. 159.8** Wide-field fundus photograph of an eye with acute myelogenous leukemia and retinal hemorrhages.

Cotton-wool spots may be the presenting abnormality that precipitates the systemic evaluation leading to the diagnosis of leukemia.<sup>42</sup> Cotton-wool spots may be caused by local factors, such as an abnormally large cell or a cluster of cells occluding retinal arterioles, and may not be related to the overall peripheral blood composition. In general, hematologic parameters are not associated

with the presence of cotton-wool spots.<sup>43</sup> Cotton-wool spots and hemorrhages can spontaneously resolve in patients with chronic leukemic disease.<sup>5</sup>

## Manifestations of Hyperviscosity

Whole-blood hyperviscosity may lead to veno-occlusive disease, microaneurysm formation, retinal hemorrhages, and retinal neovascularization. The most common manifestation is probably a mild, or “hyperpermeable,” central retinal vein occlusion (Fig. 159.9). A systemic hyperviscosity state should be suspected in patients with simultaneous, bilateral retinal vein occlusion. Also, the very high white cell count may lead to a hyperviscosity state that results in poor absorption of cerebrospinal fluid, creating a clinical picture similar to that of benign intracranial hypertension with bilateral disc swelling.<sup>44</sup>

**FIG. 159.9** (A) Central retinal vein obstruction in a patient with systemic hyperviscosity. The findings were bilateral and symmetric. (B) After lowering of the blood viscosity, the fundus appearance is normalized.

Peripheral retinal microaneurysms in leukemic patients were originally described by Duke et al.<sup>45</sup> and subsequently by Jampol et al.<sup>46</sup> Duke et al.<sup>45</sup> found that 50% of patients dying with chronic leukemia had peripheral microaneurysms. None were seen in patients with the acute leukemias. Seven of nine patients with chronic myelogenous leukemia and three of 10 patients with chronic lymphocytic leukemia had this finding, but it was not present in any of the 21 patients with acute leukemia.<sup>45</sup> Kincaid and

Green<sup>1</sup> saw only one case in their large series. They noted that trypsin digest of the retina was essential or else the change would be overlooked on histopathologic examination.

Peripheral retinal neovascularization has been reported in patients with chronic myelogenous leukemia in association with peripheral capillary nonperfusion. Most cases have associated extreme leukocytosis or thrombocytosis.<sup>47-50</sup> Presumably, the hyperviscosity state leads to peripheral nonperfusion and subsequent development of retinal neovascularization, as in patients with proliferative sickle retinopathy.

Morse and McCready<sup>50</sup> reported on a 32-year-old patient with chronic myelogenous leukemia and retinal neovascularization. The peripheral white blood cell count was  $340.5 \times 10^9/L$  and subsequently rose to  $524 \times 10^9/L$ . The fasting blood sugar value was normal, as was the hemoglobin electrophoresis study. No paraproteins were present. A fluorescein study highlighted multiple sea fans, and obliteration of the terminal arterioles was apparent. Frank and Ryan<sup>47</sup> described a 30-year-old patient with a subhyaloid and vitreous hemorrhage who had a white blood cell count of  $250 \times 10^9/L$  related to chronic myelogenous leukemia. Numerous sea fans were apparent, and a glucose tolerance test and hemoglobin and serum protein electrophoresis studies were negative.<sup>50</sup> Like Morse and McCready,<sup>50</sup> Frank and Ryan<sup>47</sup> believed that the pathogenic mechanism was related to increased blood viscosity, as in patients with complications of Waldenström macroglobulinemia or polycythemia. Kincaid and Green,<sup>1</sup> however, did not see any cases of peripheral retinal neovascularization in their series.

Levielle and Morse<sup>48</sup> described a patient with chronic myelogenous leukemia who had a relatively low ( $33.7 \times 10^9/L$ ) white blood cell count. In general, the blood viscosity begins to increase remarkably only with white blood cell counts of  $>50 \times 10^9/L$ .<sup>51</sup> In Levielle's case report, the patient had an elevated platelet count of  $988 \times 10^9/L$ , and the peripheral neovascularization was attributed to this elevation. However, the authors did not emphasize that their patient also had an 11-year history of diabetes mellitus; therefore diabetic retinopathy also may have contributed to retinal capillary non-perfusion and formation of peripheral neovascularization.<sup>51</sup>

Melberg et al.<sup>52</sup> described the effect of acute lymphocytic leukemia on the progression of mild diabetic retinopathy in a 16-year-old girl. The patient developed bilateral rubeosis, and after aggressive laser and vitrectomy, her vision declined to 20/200 bilaterally as a result of macular ischemia. The accelerated course of diabetic retinopathy correlated most closely with the anemia accompanying her leukemia and its treatment.

Wiznia et al.<sup>53</sup> reported on concurrent optic disc and retinal neovascularization in an 18-year-old woman with acute lymphocytic leukemia who underwent therapy. They described progression of the neovascularization caused by the additive effects of radiation retinopathy and chemotherapy, resulting in macular traction detachment. The authors postulated that toxic effects of chemotherapy when combined with radiation therapy could lead to a more severe form of ischemic retinal vasculopathy than would be encountered with acute lymphocytic leukemia alone.<sup>53</sup>

The mechanism of the retinal hemorrhage seen in patients with leukemia is not yet known. The hemorrhages may be caused by an associated anemia or thrombocytopenia. Although commonly associated with severe leukocytosis, white-centered hemorrhages may be present regardless of the degree of leukocytosis.<sup>54</sup>

Some authors believe that the platelet count is more predictive than the hematocrit for the presence or absence of retinal hemorrhages.<sup>55</sup> Kincaid and Green<sup>1</sup> summarized the issue in 1983 and wrote that there is no close correlation between the degree of retinal involvement and red blood cell, white blood cell, or platelet levels. We have prospectively correlated the ocular findings with hematologic values on presentation in our series of 120 cases examined within a few days of diagnosis.<sup>56</sup> We found a strong association between low platelet counts and intraretinal hemorrhages. Acute lymphoblastic leukemia patients with hemorrhages had a mean platelet count of  $26.9 \times 10^9/L$ , whereas patients without hemorrhage had mean counts of  $116.2 \times 10^9/L$  ( $p \leq .0001$ ); acute myelogenous leukemia patients with platelet counts of  $<15 \times 10^9/L$  were more likely than those without such low counts to have intraretinal hemorrhages (55% vs. 29%). In addition, there was also a statistical difference between hematocrits (a mean of 20.3 mL/dL for patients with hemorrhage and a mean of 26.2 mL/dL for

patients without hemorrhage). However, a two- or three-point difference in the hematocrit is not of clinical importance. We believe that the platelet count plays a much stronger role in determining the presence or absence of intraretinal hemorrhage.<sup>56</sup> Furthermore, on presentation, hematologic values were not found to be correlated with the presence of cotton-wool spots.

The presence of specific retinal manifestations of leukemic retinopathy and the subsequent risk of developing an intracranial hemorrhage was reported by Jackson et al.<sup>57</sup> They reported a fivefold relative risk of an intracranial hemorrhage developing in those patients with macular hemorrhages compared with those patients without such hemorrhage. No increased risk of intracranial hemorrhage existed with the presence of non-macular intraretinal hemorrhages, white-centered hemorrhages, or cotton-wool spots. Therefore, patients with macular hemorrhages may require close monitoring for the possible development of intracranial hemorrhages, and these patients may need platelet transfusions if such an intracranial hemorrhage occurs.

## Opportunistic Infections

Opportunistic infections are common in immunosuppressed patients. Cytomegalovirus (CMV) is one of the most common causes of infectious retinitis in patients with altered immune status (Fig. 159.10).<sup>58</sup> HTLV-1-associated adult T-cell leukemia can also present with a necrotizing retinal vasculitis.<sup>59</sup> Various herpesviruses also can cause infectious retinitis.<sup>60</sup> An unusual case of mumps uveitis in a patient with acute lymphocytic leukemia has been reported.<sup>61</sup> A case of progressive outer retinal necrosis (PORN) after bone marrow transplantation in a 15-year-old boy with acute myelogenous leukemia has been reported by Lewis et al.<sup>62</sup> The course of the infection was so rapid that antiviral therapy was unable to save the patient's vision.

**FIG. 159.10** Cytomegalovirus retinitis. (Courtesy of James P. Dunn.)

Among parasitic infections, ocular toxoplasmosis is the most common. Fungal intraocular involvement is a frequent and severe problem.<sup>63</sup> One should consider opportunistic infection as a cause of retinal infiltration even in the absence of vitritis in immunocompromised patients.<sup>64</sup> If a diagnostic dilemma exists, vitreous biopsy with 23- or 25-gauge vitrectomy may be helpful in identifying infectious etiologies.<sup>65,66</sup> Hematologic malignancy has been reported as a common predisposing systemic factor for intraocular fungal infections, and ophthalmologists should have a high index of suspicion when examining patients with myeloproliferative disorders.<sup>67,68</sup>

## Prognosis

Leukemic retinopathy usually is seen when the patient is in relapse and is related to coexisting anemia.<sup>22</sup> Many authors had previously observed that fundal changes did not appear to carry prognostic significance.<sup>69</sup> However, the relationship of leukemic retinopathy to patient survival was evaluated prospectively in 54 patients by Abu el-Asrar et al.<sup>70</sup> Among the 35% of patients with leukemic retinopathy, the mean survival rate was significantly shorter for those patients with cotton-wool spots than those without them (169 vs. 609 days). Patients with cotton-wool spots were eight times more likely to die in the follow-up period than patients without this

finding, possibly because of severe bone marrow dysfunction. The prognostic significance of leukemic retinopathy in childhood leukemia was evaluated in 63 patients by Ohkoshi and Tsiaras.<sup>71</sup> The 5-year survival rate was significantly lower in those with leukemic retinopathy on presentation than in those without ophthalmic involvement (21.4% vs. 45.7%). These two studies suggest that patients with clinical leukemic retinopathy may have more aggressive systemic disease that might lead to a worse prognosis.

Although peripheral blood counts or retinal hemorrhages and exudates do not seem to be predictors of systemic relapse or mortality, retinal infiltrates defined as whitish irregular patches near or around retinal vessels have been associated with leukemia that has a worse prognosis. Gross leukemic infiltrates, as illustrated in [Fig. 159.2](#), have been identified in moribund patients.

## Treatment

Intraocular manifestations of leukemia usually are not treated directly. Rather, systemic chemotherapy is administered in an attempt to control the underlying systemic problem.<sup>72,73</sup> In addition, recent studies have demonstrated that patients with central nervous system leukemic involvement may benefit from both intravenous and intrathecal chemotherapy without the need for cranial irradiation.<sup>74</sup> General supportive measures (e.g., blood transfusions) may also be recommended for patients with severe anemia or thrombocytopenia.

It is not known whether or not most systemic chemotherapeutic agents penetrate into the eye. The eye does appear to be beyond the reach of intrathecal chemotherapy.<sup>75</sup> When definite leukemic infiltrates fail to respond promptly to systemic or intrathecal chemotherapy, ocular radiation may be recommended. Varying doses have been used,<sup>1</sup> and consultation with an experienced radiation oncologist is essential. Hoover et al. reported on their follow-up of 82 survivors of leukemia treated at their institution and found only minimal ocular morbidity (posterior subcapsular cataracts in 52%).<sup>76</sup> Lopez et al. described the occurrence of radiation retinopathy after low doses of teletherapy in five of eight

patients with leukemia who were treated with high-dose chemotherapy in the setting of bone marrow transplantation.<sup>77</sup> They suggest that high-dose chemotherapy may increase the susceptibility for the development of radiation retinopathy at otherwise safe radiation doses. Webster et al. reported on a similar case of ischemic retinopathy complicating bone marrow transplantation that was combined with the use of campath-1G (for suppression of graft-versus-host disease).<sup>78</sup> Therefore, treatment with cranial or orbital radiation may result in radiation retinopathy, and follow-up evaluation is necessary to detect this potential complication. Hyperleukocytic retinopathy may be managed by leukapheresis. Mehta et al. reported on three patients with hemorrhages and exudates in a pattern consistent with a state of severe hyperviscosity.<sup>79</sup> They noted retinal venous distention, scattered hemorrhages, and optic disc edema in a pattern of a mild central retinal vein occlusion. The patients had peripheral white blood cell counts of 129 , 379 , and 1 043  $\times 10^9/L$ , respectively. Two patients improved rapidly after leukapheresis. In addition, the authors cite a number of other cases in which the procedure has been used successfully.<sup>79</sup>

## Lymphomas

Lymphomas are classified as either Hodgkin lymphoma or non-Hodgkin lymphoma. In addition, malignant lymphomas are divided into primary intraocular lymphoma and secondary intraocular lymphoma. Primary intraocular lymphoma involves primary central nervous system lymphoma, whereas secondary intraocular lymphoma involves a metastasis from a primary visceral lymphoma. The incidence of neoplastic intraocular involvement in patients with lymphomas is probably much less than that in patients with various leukemias. Lymphoid infiltration of the uvea, formally termed reactive lymphoid hyperplasia, is rare and usually is not associated with systemic disease.<sup>80</sup>

## Non-Hodgkin Lymphoma

Non-Hodgkin lymphomas constitute approximately 5% of all

newly diagnosed cancers in the United States. They are predominantly of B-cell lymphocytic origin, although some may be derived from T cells.<sup>81</sup> Ocular manifestations in this disease occur in two distinct settings, systemic non-Hodgkin lymphoma and primary central nervous system (CNS) non-Hodgkin lymphoma.<sup>82</sup> Systemic non-Hodgkin lymphoma most commonly involves the internal structures of the eye, gaining access by the choroidal tissues.<sup>83–86</sup> Ocular involvement is often asymmetric and most commonly affects individuals in the sixth decade of life and beyond (although a case has been reported in a 15-year-old boy<sup>85</sup>).

Until recently, primary ocular lymphoma has been an uncommon cause of chronic vitritis and has represented one of several sites of multifocal primary central nervous system lymphoma (PCNSL), also referred to as non-Hodgkin lymphoma of the central nervous system (NHL-CNS).<sup>87</sup> In up to half of the cases of PCNSL, the eyes were the initial site of disease and it is frequently bilateral.<sup>82,85</sup> In a large retrospective study of 221 patients with PCNSL, the median age at diagnosis was 60 years and ocular disturbances and behavioral/cognitive changes were the most common presenting symptoms.<sup>88</sup> The correct diagnosis is often not established until late in the disease course, since this condition often masquerades as chronic uveitis, despite the absence of external signs of inflammation.<sup>35</sup> Approximately 60–80% of patients who have ocular lymphoma at presentation develop cerebral lymphoma with a long enough follow-up period.<sup>83</sup> Metastasis of PCNSL outside the CNS is seen in only up to 8% of autopsy series. In the past decade there has been a steady increase in the frequency of reports of primary intraocular lymphomas.<sup>89</sup> This increased incidence of PCNSL has been reported in both immunocompromised patients (from AIDS and from organ transplantation) and immunocompetent patients.<sup>85,90</sup> It is postulated that immunocompromised patients manifest with an abnormal response to the Epstein–Barr virus (EBV) through development of a monoclonal B-cell proliferation.<sup>91</sup> Ocular lymphoma and PCNSL are restricted to the central nervous system and are not a consequence of metastasis of systemic lymphoma.

Retinal hemorrhages and cotton-wool spots related to anemia or thrombocytopenia are common in patients with non-Hodgkin

lymphoma, but direct retinal involvement in patients with systemic lymphoma is extremely rare. Lewis and Clark<sup>92</sup> described a patient with well-differentiated lymphocytic lymphoma who had massive perivenous infiltrates (Fig. 159.11). The patient was treated with 3000 cGy of external beam radiation, and a partial response occurred. The authors believed that the most likely cause was lymphomatous infiltration, although no pathologic examination was performed.<sup>92</sup> The appearance of the retina was similar to that seen in frosted-branch angiitis.<sup>93</sup> Topilow et al. described a case of lymphomatous infiltration of the retina simulating progressive outer retinal necrosis.<sup>94</sup> Ocular lymphoma should be considered in the differential diagnosis of retinal vasculitis or necrotizing retinitis.<sup>81,86,95</sup> Gass et al. described two patients with the presenting symptom of a flecked retina simulating fundus flavimaculatus in one eye months before developing signs and symptoms of the systemic form of non-Hodgkin lymphoma.<sup>96</sup> Shah et al. reported the presence of multiple white spots at the level of the outer retina resembling the multiple evanescent white dot syndrome.<sup>97</sup> Marmor et al. reported on a patient with poorly differentiated lymphocytic lymphoma who subsequently developed histiocytic lymphoma.<sup>98</sup> This patient was thought to have lymphomatous involvement of the optic nerve head, although pathologic study demonstrated cytomegalovirus (CMV) in the optic nerve head.<sup>98</sup> Fredrick et al. described a large peripapillary choroidal lymphomatous mass as the presenting manifestation of systemic lymphoma.<sup>99</sup> In addition, Jensen et al. reported an intraocular T-cell lymphoma mimicking a ring melanoma as the first manifestation of a systemic lymphoma.<sup>100</sup> We examined a patient with non-Hodgkin lymphoma who had massive infiltration of the optic disc with subsequent development of a central retinal artery occlusion (Fig. 159.12).<sup>101</sup>

**FIG. 159.11** Massive perivascular infiltrates in a patient with well-differentiated lymphocytic lymphoma.

Characteristic yellowish placoid RPE detachments may occur in some cases of ocular lymphoma, and the malignant cells are found in the vitreous, the retina, and between the RPE and Bruch's membrane.<sup>102</sup> Liu and colleagues have demonstrated that spectral domain optical coherence tomography (OCT) imaging may reveal hyperreflective material accumulation in the intraretinal and subretinal pigment epithelial spaces in eyes with primary central nervous system lymphoma.<sup>103</sup> The OCT findings may be useful in

aiding the diagnosis of intraocular lymphoma, and this imaging modality may also be used to assist in monitoring the progression or regression of the retinal involvement. These tumorous RPE detachments can resolve spontaneously, resulting in the formation of disciform scars or areolar atrophy of the RPE. Indirect effects of systemic lymphoma on the eye have also been reported. Cohen et al. described an 11-year-old girl with a central retinal artery occlusion in association with a systemic T-cell lymphoma.<sup>104</sup> They postulated that a paraneoplastic hypercoagulopathy was responsible, although they could not rule out the possibility of a lesion behind the nerve head. Das et al. reported on a 19-year-old man with retinopathy caused by hypertension, which was caused by renal involvement by non-Hodgkin lymphoma.<sup>105</sup>

Cytologic examination of vitreous biopsies is the benchmark for diagnosis of intraocular lymphoma.<sup>86,87,94,106–112</sup> A diagnostic vitrectomy with prompt and careful cytopreparatory techniques is essential for the detection of lymphoma cells. Lymphoma cells are typically 2–4 times the size of normal lymphocytes and display high nuclear/cytoplasmic ratios, prominent nucleoli, nuclear pleomorphism, and coarse chromatin patterns.<sup>106,112,113</sup> The skills and experience of the pathologist interpreting the specimen are critical in making the diagnosis in conjunction with the use of flow cytometry to define the cellular origins. Monoclonal proliferations of B cells through polymerase chain reaction (PCR) have been used to increase the sensitivity of vitreous biopsies performed in patients suspected of having B-cell lymphoma.<sup>114</sup> In addition, interleukin-10 and interleukin-6 concentrations in the vitreous may be correlated with the clinical activity and number of malignant cells.<sup>115–117</sup> Elevated levels of interleukin-10 therefore should alert the pathologist to the presence of malignant cells in the vitreous specimen.<sup>112,117</sup>

Other routes for tissue biopsy include subretinal aspiration biopsy,<sup>118,119</sup> fine-needle aspiration biopsy,<sup>120,121</sup> and transscleral chorioretinal biopsy.<sup>122</sup> In some cases, concurrent vitreous biopsies may be cytologically negative, and the diagnosis may be made only with the subretinal biopsy (Fig. 159.13).

**FIG. 159.13** (A) Non-Hodgkin lymphoma involving the retina and vitreous of a middle-aged man. Immunocytologic analysis of the vitreous biopsy was negative. (B,C) Concurrent subretinal aspiration biopsy of an isolated midperipheral lesion in the same patient demonstrated cells of non-Hodgkin lymphoma. (Courtesy of Daniel Martin, MD.)

Neuroimaging has been shown to have a low sensitivity for differentiating intraocular lymphoma from uveitis or melanoma.<sup>123</sup> Ultrasonography has been useful in documenting the extent of posterior segment involvement before therapy and may be useful in evaluating the response to treatment.<sup>124</sup> All patients with positive vitreous biopsies should undergo cerebrospinal fluid cytologic examination.

The paraneoplastic syndrome of bilateral diffuse uveal melanocytic proliferation has been reported in the single case of a patient with non-Hodgkin systemic lymphoma.<sup>125</sup>

## Hodgkin Lymphoma

Hodgkin disease is a malignant lymphoma with protean manifestations. The disease is characterized by painless swelling of the lymph nodes, and Reed–Sternberg cells are seen on histopathologic examination. Barr and Joondeph<sup>84</sup> described a patient whose initial manifestation of Hodgkin disease was periphlebitis, focal chorioretinitis, vitritis, and optic disc edema (Fig. 159.14). The retinitis and vitritis resolved after 4000 cGy of radiation therapy.<sup>84</sup> The authors summarized a number of previous reports of ophthalmic manifestations of Hodgkin disease, including bilateral exudative retinal detachment, cotton-wool spots with retinal hemorrhages, and necrotizing retinitis. Patients with “numerous white deposits in the retinal periphery,” chorioretinitis, Roth spots, and perivasculitis have been reported.<sup>43,84</sup> Histopathologic evidence of cotton-wool spots has been reported in patients with Hodgkin disease.<sup>126</sup>

**FIG. 159.14** (A) Mild disc swelling, vitritis, and foci of periphlebitis in a patient with Hodgkin disease. (B) The periphlebitis is more marked in the left eye. (C) Frame from a fluorescein angiogram. Note disc hyperfluorescence, perivascular staining, and foci of hyperfluorescence at the level of the retinal pigment epithelium. (D) Later-phase angiogram in the left eye. Note perivascular staining. (E) Lymph node biopsy specimen typical of nodular sclerosing Hodgkin disease. (Reproduced with permission from Barr CC, Joondeph HC. Retinal periphlebitis as the initial clinical finding in a patient with Hodgkin's disease. *Retina* 1983;3:253-7.)

Direct demonstration of tumor cells in ocular tissues is rare in patients with Hodgkin disease. Primbs et al. described a patient

with primarily anterior uveitis at presentation who had no malignant cells in the vitreous. Reed–Sternberg cells were seen in the anterior chamber and trabecular meshwork.<sup>127</sup> Mosteller et al. reported on a patient with anterior and posterior uveitis, pars plana exudates, perivascular sheathing, small, round, discrete white retinal lesions, and cystoid macular edema. A vitrectomy specimen demonstrated only acute and chronic inflammatory cells, and no tumor cells were seen.<sup>128</sup>

In one published report, a patient with Hodgkin disease had widespread severe destruction of the retina that was believed to represent a manifestation of drug toxicity.<sup>129</sup> However, the patient also had concomitant disseminated herpes zoster infection, and viral retinitis of this type is known to occur in immunocompromised hosts.<sup>130</sup> This association suggests that many cases previously diagnosed as intraocular Hodgkin disease probably represent secondary viral retinitis. Diddie et al. reported the histopathologic findings of a patient with Hodgkin lymphoma who had herpesvirus infection.<sup>131</sup> Toy and Knowlden summarized the findings of a patient with CMV retinitis who had been misdiagnosed as having Hodgkin lymphoma deposits.<sup>132</sup>

Opportunistic infections are common in patients with Hodgkin lymphoma. Toxoplasmic uveitis and chorioretinitis,<sup>133</sup> *Nocardia* infection,<sup>134</sup> and virtually all viral infections of the herpes family have been previously reported.<sup>43</sup>

## Treatment of Lymphoma

Management of ocular involvement by non-Hodgkin and Hodgkin lymphoma consists of systemic and/or intrathecal chemotherapy with possible radiation therapy for CNS disease that is recalcitrant to chemotherapy.<sup>112</sup> The most common systemic agents used include methotrexate, cytarabine, vincristine, rituximab, cyclophosphamide, and steroids. The optimal treatment for PCNSL is still controversial.

In the past few years, ophthalmologists have employed the use of intravitreal injection of chemotherapeutic agents as an alternative to external beam radiation of the eye. Reports have demonstrated successful use of intravitreal methotrexate and rituximab.<sup>135,136</sup>

The prognosis for survival in untreated disease is poor, but it may be improved with early and aggressive therapy.<sup>83</sup> Even with aggressive modern therapy, the median survival is expected to be about 3 years.<sup>137,138</sup>

## Mycosis Fungoides

Mycosis fungoides is a malignant T-cell lymphoma arising in the skin. There are three stages of the disease: (1) a prolonged phase of premycotic/eczematous skin lesions; (2) a phase characterized by infiltrative plaque lesions; and (3) a final phase of frank cutaneous tumor. Histopathologically, mycosis fungoides is characterized by cellular infiltrates of atypical lymphoid cells in the dermis (Pautrier's microabscesses), clusters of atypical lymphoid cells, and mycosis cells/lymphoid cells with large, irregular, and deeply indented "cerebriform" nuclei.<sup>139</sup> Systemic involvement occurs late in the course of the disease and may include virtually all organ systems.<sup>140</sup> Commonly these extracutaneous sites of involvement include the lymph nodes, liver, spleen, and CNS. Most affected individuals develop the disease in the fifth decade of life, and many die of unrelated causes before widespread involvement.

Mycosis fungoides involves the eye in up to one-third of individuals and tends to involve the external eye and adnexa much more commonly than the intraocular structures.<sup>139</sup> Only a few cases with intraocular involvement have been reported. Keltner et al. saw a patient with disc swelling and macular edema. The disc swelling was probably related to papilledema because lethargy, confusion, and focal neurologic signs were observed.<sup>139</sup> The patient initially responded to radiation therapy, steroids, and intrathecal methotrexate but subsequently developed swelling and pallor of both discs and infiltration of the retina and vitreous. On histopathologic examination, atypical cells and lymphocytes, as well as polymorphonuclear cells, were seen in the vitreous. Similar atypical cells infiltrated the retina, and a perivascular lymphocytic infiltrate was noted. Rossi reported on a patient with bilateral papilledema, venous stasis, retinal edema, and retinal hemorrhages.<sup>141</sup> Gartner described a patient with choroidal involvement chiefly characterized by perivascular granulomas.<sup>142</sup>

Foerster presented the histopathologic findings from a patient with a blind, painful eye who had diffuse neoplastic subretinal pigment epithelial infiltrates.<sup>143</sup> Necrotic tumor cells were also seen in the vitreous. A 16-year-old girl who died of visceral mycosis fungoides had no light perception in either eye or bilateral disc swelling. Malignant cells infiltrated the surrounding peripapillary retina.

The largest series of patients with mycosis fungoides reported in the ophthalmic literature is that of Stenson and Ramsay.<sup>144</sup> A total of 30 consecutive patients with mycosis fungoides were examined; 11 had positive findings related to mycosis fungoides, although only four had posterior segment changes (three patients had optic atrophy, and one patient had recurrent panuveitis). Erny et al. reported on the clinical and histopathologic findings in a 48-year-old man with vitritis and subretinal lesions that proved to be malignant T-cell infiltrates in the retina and the vitreous and between the RPE and Bruch's membrane.<sup>145</sup> Leitch et al. established the diagnosis in a 61-year-old woman with the aid of a vitreous biopsy.<sup>146</sup> Several of these reports demonstrated intraocular infiltration as an early manifestation of extracutaneous disease.<sup>139,145,146</sup>

## Burkitt Lymphoma

Burkitt lymphoma was originally described in 1958 in a review of a series of patients from Kampala, Uganda.<sup>147</sup> It is a poorly differentiated lymphocytic lymphoma with characteristic clinical and histologic patterns. Burkitt lymphoma is the most common childhood tumor in Africa, but it occurs only rarely in the United States.<sup>148</sup>

Karp et al.<sup>148</sup> described a case in which the choroid and much of the interior of the globe was diffusely infiltrated by tumor. Burkitt lymphoma commonly involves the orbital structures, and the authors did not rule out the possibility that an invasive orbital neoplasm secondarily involved the intraocular structures. Feman et al.<sup>149</sup> described a patient who had a white patch over the disc associated with many small retinal hemorrhages. Histopathologic study demonstrated diffuse neoplastic infiltration of the optic disc and peripapillary retina. The infiltrate contained scattered

histiocytes (Fig. 159.15). The choroid was uninvolved, but scattered cells were present in the vitreous. Definite primary intraocular Burkitt lymphoma is exceedingly rare.

**FIG. 159.15** Paramacular region showing tumor infiltration, predominantly of the inner retina, and lack of choroidal involvement. Note “starry-sky” appearance of tumor infiltrate. (Courtesy of Foos RY; reproduced with permission from Feman SS, Niwayama G, Hepler R, et al. “Burkitt tumor” with intraocular involvement. *Surv Ophthalmol* 1969;14:106–11.)

## Multiple Myeloma and Waldenström Macroglobulinemia

Multiple myeloma is a plasma cell neoplasm that can exhibit a wide range of systemic and ocular signs and symptoms.<sup>150</sup> Pars plana cysts are common and can be a striking ophthalmic finding.<sup>150</sup> Uveal involvement has been reported by Bronstein.<sup>151</sup> The most common retinal findings include manifestations of anemia and thrombocytopenia, such as flame-shaped or white-centered hemorrhages and nerve fiber layer infarcts.<sup>152</sup> In one report these findings were seen in 8 of 22 patients with multiple myeloma.<sup>40</sup>

Microaneurysm formation may be apparent, most frequently in the retinal periphery and midperiphery.<sup>153,154</sup> The cause of this change is not certain. It may be related to hyperviscosity,<sup>155</sup> although a frank hyperviscosity syndrome is not as common in

patients with multiple myeloma as it is in patients with, e.g., Waldenström macroglobulinemia. If hyperviscosity is severe, retinal changes similar to those described in Waldenström macroglobulinemia may be seen.<sup>156</sup> Serous and exudative retinal detachments associated with multiple myeloma have also been reported.<sup>60,157</sup>

A clinicopathologic review of multiple myeloma and its ocular manifestations has been presented by Knapp et al.<sup>150</sup> In this report, the patients with retinopathy had lower hematocrit levels and platelet counts than those without retinopathy. In many patients the retinopathy cleared with treatment. The presence of retinal changes did not appear to alter the prognosis.

Patients with Waldenström macroglobulinemia have an abnormal elevation of their IgM fraction of plasma proteins. The retinal findings are chiefly those of systemic hyperviscosity, although manifestations of anemia or thrombocytopenia may be seen. Clinically, patients may present with bilateral venous dilation, which is difficult to differentiate from the findings of central retinal vein obstruction.<sup>158</sup> In addition to the picture of venous obstruction, microaneurysms associated with peripheral retinal neovascularization may be present. Peripheral capillary nonperfusion of the retina has also been reported.<sup>159</sup> Case reports have also documented the formation of serous retinal detachment.<sup>160</sup> The findings may be reversible when the hyperviscosity state is normalized (see [Fig. 159.9](#)). Visually symptomatic patients may benefit from plasmapheresis.<sup>153</sup>

## **Prognosis**

## **Introduction**

Primary vitreoretinal lymphoma (PVRL) is an ocular subset of primary central nervous system lymphoma (PCNSL), a rare, extranodal, non-Hodgkin's lymphoma associated with poor survival.<sup>1</sup> PVRL is typically an aggressive diffuse large B-cell lymphoma, although rare cases of T-cell lymphoma occur, usually secondary to human T-cell lymphotropic virus type 1 (HTLV-1) or metastatic T-cell lymphoma.<sup>1,2</sup> PCNSL originates in the brain parenchyma, spinal cord, leptomeninges, and eyes.<sup>3</sup>

As vitreoretinal manifestations predominate, PVRL is currently the preferred terminology. Former descriptors such as “reticulum cell sarcoma” and “microgliomatosis” misleadingly imply malignant transformation of reticulum or microglial cells.<sup>4,5</sup> Other terms, including primary intraocular lymphoma (PIOL or PCNSL-O), have also been used. It is important to distinguish aggressive PVRL from more indolent forms of ocular adnexal and uveal lymphoma. The vast majority of the latter are extranodal marginal zone lymphoma (EMZL) and follow a clinical course similar to systemic low-grade lymphoma.<sup>6</sup>

## Epidemiology

PCNSL accounts for 1–2% of all extranodal lymphoma and 3–5% of primary central nervous system (CNS) tumors.<sup>7</sup> From 1973 to 1997, the incidence of PCNSL increased threefold, due to the rise in cases of human immunodeficiency virus (HIV).<sup>8</sup> PCNSL develops in up to 6% of patients with acquired immune deficiency syndrome (AIDS).<sup>9</sup> An analysis of recent Surveillance, Epidemiology, and End Results data determined that the incidence of PCNSL peaked in 1995, and has since declined in individuals under the age of 65 years, while rates continue to increase in those aged 65–74 years.<sup>10</sup> The age-adjusted incidence of PCNSL in the United States is 4.8 per million population.<sup>8</sup> PCNSL affects fewer than 2000 individuals annually in the United States.<sup>3</sup>

While PVRL is frequently seen in the setting of PCNSL, its incidence is unknown due to the paucity of cases. Between 1999 and 2002, approximately 100 new cases of PVRL were reported in the United States.<sup>11</sup> The association between PVRL and PCNSL is variable, with CNS disease manifesting prior to, following, or

simultaneously with ocular presentation. Nearly 25% of patients with PCNSL will have concomitant vitreoretinal lymphoma at the time of CNS diagnosis.<sup>12</sup> Conversely, 56–90% of individuals with PVRL will ultimately develop CNS involvement over a follow-up of 8–29 months.<sup>13,14</sup> Among immunocompetent individuals, the peak incidence of PVRL occurs between ages 50 and 70 years. In the immunocompromised population, PVRL occurs in younger individuals.<sup>15</sup> There are no known racial or ethnic associations. Studies have suggested a gender bias, with women more commonly affected than men by a 2 : 1 ratio.<sup>16</sup>

## Etiology and Pathogenesis

PCNSL is believed to originate from late-germinal or post-germinal center lymphoid cells; however, the neurotropic mechanism by which these cells localize to the CNS remains uncertain.<sup>17</sup> It has been hypothesized that the trafficking of lymphoma cells from the brain to the eye and vice versa involves direct invasion of the optic nerve, seeding through shared venous drainage, or common integrin expression of these organs.<sup>17</sup>

Animal models have improved our understanding of PVRL pathogenesis.<sup>18</sup> Early murine models used intraperitoneal or intravitreal injection of mouse T-cell lymphoma.<sup>19–21</sup> More recent murine models have employed B-cell lymphomas to closely mimic human disease.<sup>22</sup> Intravitreal injection of human B-cell lymphoma (cell line CA46) in severe combined immunodeficient (SCID) mice followed by sacrifice at sequential time points revealed tumor infiltration at the retinal surface, followed by migration through the retina, progression within the subretinal space, and eventual spread to the choroid. Lymphoma within the CNS was also observed.<sup>22</sup> Human CD20-transfected murine B-lymphoma cells (38C13 CD20<sup>+</sup>) inoculated into the vitreous cavity and the caudate nucleus of immunocompetent syngeneic mice have revealed lymphoma distribution in the vitreous, subretinal space, anterior chamber, and orbit. Involvement of the CNS was observed only in mice that underwent inoculation into the caudate nucleus.<sup>23</sup>

Infectious agents may play a role in lymphomagenesis. Epstein–Barr virus (EBV) infection of B-lymphocytes in the absence of T-

suppressor lymphocytes results in uncontrolled lymphocytic proliferation. Interestingly, EBV is frequently detected in AIDS patients with PCNSL, and the disease usually has a more aggressive course;<sup>24</sup> however, the same association is not observed in immunocompetent individuals with PVRL.<sup>25</sup>

## Clinical Findings

### Ophthalmic Findings

Diagnosis of PVRL is challenging, as the clinical findings can be nonspecific and mimic inflammatory and infectious uveitis. Individuals may be asymptomatic; however, more than half have painless, decreased visual acuity or floaters.<sup>26</sup> Many are diagnosed during ophthalmic screening in the setting of PCNSL. Findings are bilateral in 80% of individuals but are frequently asymmetric.<sup>22</sup>

The hallmark feature of PVRL is vitreous cells and/or subretinal pigment epithelium (RPE) infiltrates of aggregated lymphoma cells (Fig. 160.1).<sup>27</sup> When present, these sub-RPE lesions are pathognomonic (Fig. 160.2).<sup>28</sup> Anterior segment findings (keratic precipitates, iris nodules, aqueous cells, and flare) are frequently encountered but are nonspecific. Other less common associations include perivasculitis (Fig. 160.3), retinal artery occlusion, exudative retinal detachment, multifocal atrophic lesions at the level of the RPE, and optic atrophy.<sup>29-31</sup>

**FIG. 160.1** A 56-year-old male presented with decreased visual acuity and floaters. On dilated fundus examination, vitreous haze and vitreous cellular condensations (A) were observed. (B) Magnetic resonance imaging of the brain showed scattered increased T2 signal intensity (*arrows*) in a periventricular distribution consistent with primary central nervous system lymphoma with vitreoretinal involvement. (C) Vitrectomy sample showed large atypical lymphocytes, necrotic lymphoid cells, and nuclear debris. Inset demonstrates characteristic nuclear membrane protrusions and a prominent nucleolus (Millipore filter; hematoxylin and eosin, original magnification  $\times 250$ ). (D) Following systemic high-dose methotrexate and intravitreal methotrexate, a significant reduction in the degree of vitreous cells was observed. (Panel C courtesy of RC Eagle Jr, MD, reproduced with

permission from Singh AD, Lewis H, Schachat AP. Primary lymphoma of the central nervous system. *Ophthalmol Clin North Am* 2005; 18:199–207.)

**FIG. 160.2** A 58-year-old female with primary central nervous system lymphoma presented with blurry vision. Fundus examination of the right eye demonstrated mild vitritis, scattered atrophic chorioretinal lesions with retinal pigment epithelium proliferation, and a white, dome-shaped subretinal infiltrates temporal to the macula.

**FIG. 160.3** A 39-year-old African American female was

initially presumed to have sarcoidosis based upon vitreous cellular condensations and peripheral vasculitis that were responsive to intraocular steroids. Subsequent neuroimaging and cerebrospinal fluid studies were positive for malignant cells consistent with primary central nervous system lymphoma with vitreoretinal involvement.

## Central Nervous System Findings

PCNSL is an aggressive malignancy; therefore diagnosis is generally established within several months of symptom onset. In contrast, the diagnosis of PVRL is frequently delayed, sometimes for years. It is not uncommon for PVRL to be misdiagnosed as posterior uveitis or more common masquerading diseases. In PCNSL, personality changes are a common presentation as the frontal lobe is the most frequent region of brain to be involved. Seizures are a rare feature of this disease.

The lesions in PCNSL tend to be periventricular in location, thus allowing access to the cerebrospinal fluid (CSF) and leptomeninges. Leptomeningeal involvement occurs in approximately 40% of cases.<sup>32</sup> Rarely, PCNSL limited to the spinal cord is observed.<sup>33</sup> The lesions are commonly multifocal, particularly in immunocompromised individuals.

## Diagnosis

The diagnosis of PVRL should be suspected in middle-aged, elderly, or immunocompromised individuals with either classic clinical features or “idiopathic” recurrent uveitis, particularly cases unresponsive to steroids. Evaluation should include a thorough history that explores questions related not only to ocular symptoms but also to cognitive function changes, neurologic deficits, and risk factors for immunosuppression. A detailed ophthalmic examination of both the anterior and posterior segment is necessary to assess disease extent and to establish laterality. In the setting of existing PCNSL, the diagnosis of PVRL is straightforward, and biopsy of an ophthalmic site is unnecessary if the clinical findings are

compatible.

In the absence of CNS disease, the diagnosis of PVRL is based upon histopathologic and cytologic features. As lymphoma is responsive to corticosteroids, these medications should be withheld until tissue biopsy is performed. Vitreous biopsy is performed in most cases. A common approach is to perform 23- or 25-gauge pars plana vitrectomy. Proper surgical techniques and handling are critical as aspirates are generally of low cellularity and fragile lymphoma cells are prone to lysis during sample collection. An undiluted vitreous sample (1–2 mL) is collected prior to the start of the saline infusion during vitrectomy.<sup>34,35</sup> Next, the infusion fluid is started, and a second diluted vitreous specimen using gentle vitreous cutting is collected in a separate syringe.<sup>36</sup> The vitreous cassette may also be submitted.<sup>37</sup> Samples should be delivered to the laboratory, without fixative, within one hour of surgery.<sup>35</sup> Repeated vitreous biopsies are frequently required to establish diagnosis. More recently, there has been a shift towards using 25-gauge sutureless vitrectomy for improved patient comfort and decreased operative times.<sup>37</sup>

When retinal or subretinal lesions are present, a retinal or subretinal biopsy is preferred. A subretinal biopsy technique using a standard three-port pars plana vitrectomy approach has been described.<sup>38</sup> An initial core vitrectomy is performed, vitreous separation is induced, and thorough vitrectomy is performed over the biopsy site. An incision is made in the overlying retina, and then suction tubing is inserted through the retinectomy so that several samples are obtained. Subretinal aspirates should be placed in a mild cytofixative, such as herpes-glutamic acid buffer mediated organic solvent protection effect (HOPE) fixative or CytoLyt® (Cytyc Corporation).<sup>35</sup> In a series of 84 patients who underwent pars plana vitrectomy, additional chorioretinal biopsy with extended immunohistochemistry and polymerase chain reaction (PCR) gene rearrangement studies were performed in three patients after vitrectomy was nondiagnostic. This technique yielded a definitive diagnosis of PVRL in each case.<sup>39</sup>

Cytology remains the gold standard for diagnosis. In a review of 221 individuals with histologically diagnosed PCNSL with ocular involvement, the subtype was diffuse large B-cell in 73%, T-cell in

2%, and not specified in 25%.<sup>40</sup> PVRL cells are typically 2–4 times larger than normal lymphocytes, are pleomorphic, and have scant cytoplasm.<sup>41</sup> The nuclei may be round, oval, or indented, with conspicuous nuclear membranes, occasional fingerlike protrusions, and multiple, prominent, eccentrically located nucleoli. Mitoses are frequently observed. Electron microscopy may demonstrate intranuclear inclusions, cytoplasmic crystalloids, pseudopodal extensions of the cytoplasm, cytosomes, and autophagic vacuoles.<sup>42</sup>

Supplemental techniques such as immunohistochemistry can be useful for identifying markers for leukocytes (CD45), B cells (CD20, CD79a, PAX-5), T cells (CD45RO), and macrophages (CD68).<sup>35</sup> Clonality can be established with the use of antibodies directed against  $\kappa$  and  $\lambda$  light chains.<sup>41</sup> Flow cytometry provides a quantitative assessment of the proportion of cells in a given sample that demonstrate these markers. PCR gene rearrangement studies can detect monoclonality of the heavy chain variable (V), diversity (D), and joining (J) immunoglobulin gene segments; however, most vitreous samples are inadequate for PCR.<sup>43,44</sup> Evaluation for gene rearrangement by PCR is most successful in tissue biopsy specimens in which DNA has been isolated by laser capture microdissection.<sup>43</sup> Measurement of interleukin (IL)-6 and IL-10 in either aqueous or vitreous fluid can also facilitate diagnosis. An elevated IL-10/IL-6 ratio is supportive of the diagnosis; however, this finding alone is not specific for PVRL.<sup>45,46</sup> More recently, *MYD88* mutations have been shown to occur frequently in PVRL and their detection may improve diagnostic yield of vitrectomy specimens.<sup>47</sup>

## Central Nervous System Involvement

Due to the high correlation between PVRL and PCNSL, collaboration with a neuro-oncologist, when available, enhances patient care. This should include neuroimaging and CSF studies. Magnetic resonance imaging (MRI) of the brain is the imaging study of choice for individuals with suspected PCNSL. High-volume (>10 mL) lumbar puncture for protein, glucose, cytology, and flow cytometry is particularly important as leptomeningeal involvement is present in up to 40% of individuals with PCNSL.<sup>32</sup>

CSF can demonstrate lymphocytic pleocytosis, elevated protein concentration, and low or normal glucose levels. Malignant cells in the CSF are diagnostic. Flow cytometry is the most sensitive and specific marker of CNS lymphoma.<sup>48</sup> Additional diagnostic procedures should include computed tomography (CT) scan of the chest, abdomen, and pelvis, testicular ultrasound in elderly men, and HIV testing.

## Differential Diagnosis

Delay in diagnosis of PVRL is common due to the nonspecific ophthalmic manifestations. In one series of 32 patients with histologically confirmed PVRL, the average interval between onset of symptoms and diagnosis was 21 months.<sup>49</sup> The differential diagnosis includes chronic anterior and posterior uveitis including sarcoidosis, syphilis, tuberculosis, birdshot retinochoroidopathy, multifocal chorioretinitis, acute posterior multifocal placoid pigmentary epitheliopathy, serpiginous choroiditis, and punctate inner choroidopathy.<sup>50</sup>

When subretinal lesions are present, choroidal metastases and amelanotic melanoma should be considered. Immunocompromised individuals with systemic lymphoma not arising from the CNS who develop retinal infiltrates are more likely to have viral or fungal retinitis than PVRL. In immunocompromised individuals, infectious diseases such as acute retinal necrosis, cytomegalovirus, toxoplasmosis, and *Pneumocystis carinii* (*P. jiroveci*) choroiditis should be considered.

Whipple disease, a multiorgan infection caused by the bacterium *Tropheryma whipplei*, can simulate PVRL. Middle-aged Caucasian men in the United States and Europe are most frequently affected.<sup>51</sup> Whipple disease has associated systemic symptoms including weight loss, diarrhea, polyarthralgia, and abdominal pain. Chronic uveitis can occur. Definitive diagnosis is based upon PCR of vitreous samples.

## Treatment

Consensus guidelines for the treatment of PVRL and PCNSL have

not been firmly established. There is a general consensus that regimens containing high-dose methotrexate (HD-MTX), with or without whole-brain radiation therapy (WBRT), yield better outcomes than regimens that do not contain HD-MTX.

## Ophthalmic Treatment

When disease is limited to the eye, local therapy with intravitreal chemotherapy and/or radiotherapy are appropriate. Intravitreal therapy (methotrexate or rituximab) has been shown to be effective.<sup>52-55</sup> Intravitreal methotrexate as a single agent was first reported in seven eyes in four patients in 1997, in which all cases achieved a complete response (CR).<sup>56</sup> In a series of 26 eyes in 16 patients with PVRL at two centers, intravitreal methotrexate (400 µg/0.1 mL saline) was given twice weekly for 4 weeks as induction, then weekly for 1 month at one center and weekly for 2 months at another center as consolidation, followed by once monthly for 1 year as maintenance. All eyes achieved remission following a maximum of 12 injections. During a median follow-up of 18.5 months, three patients from the first center developed relapsed PVRL and were treated following the same protocol with complete remission.<sup>53</sup> In 44 eyes in 26 patients treated with the same induction–consolidation–maintenance regimen, clinical remission was achieved following a mean of 6.4 injections and 95% of eyes required 13 or fewer injections for a CR.<sup>57</sup> No relapse was observed after follow-up ranging from 41 to 107 months.<sup>57</sup> Ocular side-effects of intravitreal methotrexate include increased intraocular pressure, cataract, conjunctival hyperemia, and transient keratopathy.<sup>53,57</sup> Early evidence suggests that rituximab may have fewer side-effects and require fewer injections to achieve remission.<sup>52,55</sup> In a prospective, interventional series, 20 eyes of 13 patients with PVRL received weekly intravitreal rituximab (1 mg/0.1 mL saline) for 4 weeks.<sup>54</sup> During a mean follow-up of 24.7 ± 6.3 months, keratic precipitates, anterior and vitreous cells, and subretinal infiltrates improved; however, recurrence developed in 55% of eyes. Ocular side-effects included transient intraocular pressure elevation in 60% and iridocyclitis in 35% of eyes.<sup>54</sup> While rituximab may be a promising therapy for PVRL either alone, or in combination with

methotrexate, additional studies are needed.

Prior to intravitreal chemotherapy, external beam radiotherapy (EBRT) was widely employed. EBRT remains an important therapy for bilateral involvement, those who may not tolerate intravitreal chemotherapy, and in individuals who cannot return for multiple injections (Fig. 160.4). EBRT to both eyes is commonly performed due to the high incidence of bilateral involvement; however, in unilateral cases, EBRT to the affected eye is preferred. Doses have ranged from 30 Gy to 50 Gy, with an average dose of 40 Gy, given in fractions of 1.5–2.0 Gy.<sup>16,58,59</sup> In a series of 19 eyes treated by EBRT, nine achieved a CR, although two eyes relapsed.<sup>58</sup> In another series of 13 patients treated by EBRT with or without chemotherapy, three had partial response (PR) and two developed recurrent disease.<sup>59</sup> In a series of 21 eyes in 12 patients, initial treatment included EBRT and systemic chemotherapy (six patients), systemic chemotherapy alone (four patients), EBRT alone (one patient), and no treatment (one patient). No ocular recurrence was observed in those receiving EBRT. Two patients who did not receive EBRT had ocular relapse.<sup>16</sup> Radiation-related side-effects include optic neuropathy, retinopathy, conjunctivitis, dry eyes, cataracts, and glaucoma.<sup>60</sup>

**FIG. 160.4** A 69-year-old male with known large B-cell lymphoma of the left frontal lobe presented with blurry vision. Dilated fundus examination revealed vitreous cells bilaterally. (A) A yellow, subretinal infiltrate was

noted temporal to the macula in the right eye. (B) At 1 month following bilateral external beam radiotherapy there was significant improvement in the subretinal infiltrate.

As many patients with PVRL subsequently develop CNS involvement, systemic chemotherapy is an attractive option offering simultaneous treatment of ocular and microscopic CNS disease. In nine patients with PVRL treated with HD-MTX at 8 g/m<sup>2</sup>, potentially cytotoxic, micromolar levels of methotrexate were detectable in aqueous and vitreous samples in most patients.<sup>61</sup> An intraocular response was reported in seven patients, with CR in six and a PR in one. Experience with combination systemic chemotherapy in PVRL is limited. A 100% response rate (11 CRs, three PRs) in 14 patients (five with intraocular involvement) treated with HD-MTX, vincristine, and thiotepa as well as intrathecal methotrexate and cytarabine has been reported. Although a high initial response was observed, the duration was limited and additional therapy was required at relapse.<sup>62</sup> High-dose chemotherapy followed by stem cell transplantation has also been reported.<sup>63</sup> Although ocular response was promising, high relapse rates and toxicity make this therapy investigational at present. The use of systemic chemotherapy has not been proven to prevent subsequent CNS involvement and may be associated with more side-effects compared with local treatment.<sup>64</sup>

## Central Nervous System Treatment

Historically, WBRT was first-line treatment for patients with PCNSL. WBRT improved median survival from 4 months to 12–18 months.<sup>65</sup> In the 1990s, HD-MTX in combination with WBRT was shown to improve median survival to 40 months.<sup>65</sup> The combination of WBRT and chemotherapy is associated with neurotoxicity in older individuals.<sup>66</sup> Chemotherapy alone is therefore used for individuals over age 60 years.<sup>65</sup> HD-MTX, either as a single agent or as part of a combination regimen, is most commonly used. High doses (3–8 g/m<sup>2</sup>) are required to reach cytotoxic concentrations in the CSF and to treat occult leptomeningeal disease.<sup>7</sup> Other regimens include high-dose cytarabine (HDAC) and ifosfamide.<sup>40</sup> An

alternative delivery method is intraarterial chemotherapy with blood–brain barrier disruption (BBBD) using mannitol infusion.<sup>65</sup> In 149 newly diagnosed PCNSL patients (with no prior WBRT) treated with BBBD and intraarterial methotrexate, an overall response rate of 82% (58% CR; 24% PR) was reported with median progression-free survival and overall survival of 1.8 and 3.1 years, respectively.<sup>67</sup> Maculopathy is a complication associated with BBBD.<sup>7</sup> In selected patients with positive CSF cytology, intrathecal methotrexate should be included in the regimen. Most recently, HD-MTX-containing multiagent regimens have been adopted as the preferred treatment for PCNSL. The timing and dose of WBRT remains uncertain, given the significant risks of late neurotoxic effects of standard-dose WBRT. Based on more recent data demonstrating preserved cognition with reduced-dose WBRT, an ongoing cooperative group study [NCT01399372] is evaluating the role of reduced-dose WBRT for upfront treatment of PCNSL.<sup>68</sup>

## Prognosis

The majority of patients (56–90%) with PVRL develop CNS disease.<sup>13,14,49</sup> In a multicenter, retrospective study of 221 patients with CNS lymphoma with vitreoretinal involvement, median progression-free survival and overall survival were 18 and 31 months, respectively.<sup>40</sup> Age less than 60 years and high initial performance status are recognized as favorable prognostic factors.<sup>69</sup> Involvement of the brainstem and leptomeninges portends poor prognosis.<sup>69</sup> The presence of vitreoretinal involvement in the setting of CNS disease does not appear to be an influential factor.<sup>69</sup> While retrospective studies have shown that ocular treatment improves disease control, no survival benefit from ocular therapy has been proven.<sup>40</sup>

Alpha-glucosidase inhibitors, for diabetes mellitus, [1058](#)

Alpha-IMS, [2346](#)

Altitude, intraocular gas and, [1960–1961](#), [1966](#)

*Alu* sequences, [716–717](#)

Amacrine cells, [378](#), [428–434](#), [428f](#)

- dopaminergic, [432–433](#), [433f](#)
- S1 and S2, [430–432](#), [430f](#)
- starburst, [433–434](#), [434f](#)

Amaurosis fugax, in ocular ischemic syndrome, [1228](#)

Amblyopia, [1255](#)

AMD, [Age-related macular degeneration \(AMD\)](#)

AMD trial (CNTF 2), [816](#)

Amelanotic choroidal melanoma, choroidal osteoma and, [2631](#)

Amelanotic malignant melanoma, [61](#)

, American Academy of Ophthalmology (AAO), [202](#)

- screening examinations for hydroxychloroquine toxicity, [1721](#)

American Association of Physicists in Medicine (AAPM), [2566–2567](#)

American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) classification criteria, for rheumatoid arthritis, [1599b](#)

American Joint Committee on Cancer (AJCC)

- classification stage, for uveal melanoma, [2527](#)
- uveal melanoma staging system, [2608](#), [2609f](#)

American National Standard Institute (ANSI) Standards “Safe Use of Lasers”, [1752](#)

American Society of Ophthalmic Plastic and Reconstructive Surgeons (ASOPRS), [2562](#)

American Telemedicine Association, on telehealth practice recommendations for diabetic retinopathy, [1130](#)

American Uveitis Society, diagnostic criteria of, for acute retinal necrosis syndrome, [1713](#), [1713t](#)

Aminoglycoside antibiotics, retinal toxicity from, [1729–1730](#)

Aminoglycosides, treatment infectious endophthalmitis, [2275](#)

Aminoguanidine, [590](#), [1041](#)

Amniotic fluid embolism, in pregnancy, [1774](#), [1775f](#)

A-mode technique, in ultrasound, [274](#)

    choroidal melanoma on, [307](#), [307f](#), [311f](#)

Amphotericin B

    for endogenous endophthalmitis, [1703–1704](#)

    intravitreal, [1704](#)

Amputation of lower extremities, diabetic retinopathy and, [1030t](#)

Amsler grid, [349–350](#), [350f–351f](#), [359f](#), [1413](#)

Amyloid, age-related macular degeneration and, [1380](#), [1411](#)

Ancestral origin, uveal melanoma and, [2516](#)

ANCHOR study, for ranibizumab, [1382](#), [1385f](#)

Ancillary tests, choroidal metastases and, [2622](#)

Anemia, in leukemia, manifestations of, [2664–2665](#)

Anesthesia

    for pneumatic retinopexy, [1945–1946](#)

    in scleral buckling surgery, [1891](#)

        examination under, [1894](#)

Ang-1, [646–647](#)

Angiofibromas, facial, [2439–2440](#), [2442](#)

Angiogenesis, [2462](#)

    definition and steps in, [1376–1377](#)

- modulators of, [1377](#)
- vascular permeability and, [1377](#)
- VEGF and, [1377](#)
- VEGF receptors and, [1377](#)
- VEGFR-2 and, [1377–1380](#), [1379f](#)

Angiographic OCT, [200](#)

Angiographic sign, in early AMD, [1285](#)

Angiography

- cystoid macular edema with vitreoretinal traction, [2201](#)
- equipment and materials needed for, [2b](#)
- fluorescein, [1–45](#)
  - in autosomal dominant radial drusen, [985](#)
  - in Best macular dystrophy, [962–963](#), [963f](#)
  - for Eales disease, [1667](#)
  - in Stargardt disease, [973–974](#), [975f](#)
- imaging of drusen and, [1312–1314](#)
- in macular translocation, [2242](#), [2250](#)
- for uveal effusion syndrome, [1487](#), [1487f](#)
- wide-angle, benefit of, [2](#)

Angioid streaks, [1438–1445](#)

- ABCC6*, *MTP* genes, in Bruch's membrane, [535](#)
- aflibercept for, [1443](#)
- anti-vascular epithelium growth factor (VEGF) treatment for, [1443–1444](#)
- bevacizumab for, [1443](#)
- combination therapy for, [1443–1444](#)
- fluorescein angiography of, [1439](#), [1441f](#)

fundus autofluorescence of, [1439–1440](#), [1440f](#)  
histopathology of, [1438](#)  
indocyanine green angiography of, [1440](#)  
laser photocoagulation for, [1441](#)  
ocular imaging and diagnosis of, [1439–1441](#)  
ocular manifestations and clinical course of, [1439](#), [1440f](#)  
photodynamic therapy for, [1442–1443](#)  
ranibizumab for, [1443](#)  
SCD and, [1206](#)  
spectral domain optical coherence tomography of, [1440](#), [1442f](#)  
surgical therapies for, [1443](#)  
swept source optical coherence tomography of, [1440–1441](#)  
systemic associations of, [1438–1439](#), [1439b](#)  
therapy for, [1441–1444](#)  
transpupillary thermotherapy for, [1441–1442](#)

Angiopoietin-like protein 4 (ANGPTL4), [642](#), [1379](#)  
Angiopoietins, [642](#), [1379](#)  
Angiostatin, [647](#)  
    lentivirus-mediated delivery of, [754](#)

Angiotensin-converting enzyme (ACE), [1587–1590](#)  
Angle closure glaucoma, in regressed ROP, [1256](#)  
Angled fiberoptic probe, [2573](#)  
Anionic dye, [47](#)  
Anisometropia, regressed ROP and, [1256](#)  
Ankylosing spondylitis, [1601](#)  
    articular and systemic disease of, [1601](#)  
    epidemiology of, [1601](#)

- ocular disease of, [1601](#)
- treatment of, [1601](#)
  - of systemic disease, [1601](#)
- Anomaloscope color-matching test
  - Moreland equation, [336](#)
  - Rayleigh equation, [335–336](#)
- Anomalous posterior vitreous detachment (PVD), [562–568](#), [563f](#)
  - macular cysts in, [565](#), [566f](#)
  - macular effects of, [565–568](#)
  - macular holes in, [567f](#), [568](#)
  - optic disc effects of, [568](#)
  - retinal breaks in, [562–565](#), [564f](#)
  - vitreomacular traction syndrome in, [565](#), [566f](#)
  - vitreoschisis in, [564f](#)
  - vitreous effects of, [562](#), [564f](#)
- Anterior chamber
  - gas in, [1967](#)
  - PFCL in, [1975](#), [1975f](#)
  - silicone oil (SO) in, [1983–1985](#)
- Anterior ciliary arteries, [1890](#), [1890f](#)
- Anterior hyaloidal fibrovascular proliferation, proliferative diabetic retinopathy and, [2124](#), [2124f](#)
- Anterior ischemic optic neuropathy (AION)
  - in ocular ischemic syndrome, [1231](#), [1232f](#)
  - in optic disc drusen, [1788](#)
- Anterior loop traction (radial fibers), [1922–1923](#)
- Anterior segment involvement, of SCD, [1205–1206](#), [1205f](#)

Anterior segment ischemia, scleral buckling surgery and, [1913](#)

Anterior uveitis, [1576](#)  
treatment of, [1581](#)

Anterior vitreous cortex (AVC), [1916](#)

Anterior-chamber paracentesis, for central retinal artery occlusion, [1142](#)

Anterior-chamber-associated immune deviation (ACAID), [660](#)

Anti-advanced glycation endproduct treatment, oxidative stress and, [590](#)

Antiangiogenic pharmacotherapy, for von Hippel-Lindau disease, [2435](#)

Antiangiogenic therapies, for proliferative diabetic retinopathy, [1115–1116](#)

Antibiotics, for endogenous endophthalmitis, [1703](#)

Antibodies, antiretinal, [1568](#)  
proteins targeted by, [1562t](#)

Anti-CD20 monoclonal antibody (Rituximab), [1568–1569](#)

Anti-CMV drug, resistance to, [1634](#)

Anticorticosteroid therapy, central serous chorioretinopathy and, [1478–1479](#)

Anti-D immunoglobulin (anti-D), for ITP, [1241](#)

Antifungals  
for endogenous endophthalmitis, [1703](#), [1704b](#)  
intravitreal, [1704](#), [1704b](#)  
therapy, advances in, [1645](#)

Antigen binding fragment, for age-related macular degeneration, [1382–1384](#)

Antigen-presenting cells (APCs), in immune regulation, [658–659](#)

Antigens, transportation of, [659](#)

Antigen-specific “deviant” systemic immune response, induction of, [2317](#)

Antiglial fibrillary acid protein (GFAP), in AMD, [632–633](#)

Anti-*Helicobacter pylori* treatment, central serous chorioretinopathy and, [1479](#)

Antimalarials, ocular complications of, [1618](#)

Antimetabolite therapy, [784–785](#)

Antimicrobials, for endogenous endophthalmitis, [1703](#)

Antioxidant defense, hormone influence on, [818](#)

Antioxidant response element (ARE), [792](#)

Antioxidant therapy, [786](#)

Antioxidants, [814f–815f](#), [817–819](#)

- for age-related macular degeneration, [1408–1410](#)
- for AMD, [1276](#)
- protection, in photoreceptor degenerations
  - clinical evidence of, [819](#)
  - preclinical evidence of, [817](#)

Antiproliferative agents

- for proliferative vitreoretinopathy, [2360](#)
- for treatment of PVR, [1871](#)

, Antiretinal antibodies, [1568](#)

- proteins targeted by, [1562t](#)

Antiretroviral therapy, HIV and, [1647](#)

Antithrombotic stockings, [2595](#)

Antituberculosis drugs, [1662t](#)

Anti-vascular endothelial growth factor (VEGF), [46](#), [833](#), [2575–2576](#)

- agents, [2236–2237](#)
- comparative effectiveness of, [1810–1811](#)

other comparative effectiveness trials of, [1811](#)  
other single, [1809–1810](#)  
subretinal tPA plus, [2236](#)  
for treatment of neovascular age-related macular degeneration,  
[1808–1809](#)  
heavy tamponade and, [1997–1998](#)  
injections, [1478](#)  
for macular translocation, [2241–2242](#)  
treatment, for branch retinal vein occlusion, [1162–1163](#)

Anti-vascular epithelial growth factor therapy, for radiation  
therapy, [1224](#)

Anti-vascular epithelium growth factor  
therapy, for ocular histoplasmosis, [1453](#), [1453f](#)  
treatment, for angioid streaks, [1443–1444](#)

Anti-VEGF Antibody for the Treatment of Predominantly Classic  
Choroidal Neovascularization in Age-Related Macular  
Degeneration (ANCHOR) Research Group, [1809](#)

Anti-VEGF therapy  
for CRVO-associated ME  
intravitreal, [1172](#)  
neovascularization during, [1174](#)  
long-term results of, [1365](#)  
for polypoidal choroidal vasculopathy, [1463](#)  
during pregnancy, [1780](#)  
safety of, [1363–1364](#)

Antiviral medication, for ARN syndrome, [1714](#)

*APC* gene, [2493](#), [2493f](#)

Aphakia

pneumatic retinopexy and, [1945](#)  
in retinal detachment, [1823](#)

Aplasia, of optic disc, [1786](#)

Apocynin, [817](#)

Apoptosis  
in retinal injury, [606–607](#), [607f](#)  
retinitis pigmentosa and, [916–917](#)

Apoptosis-inducing pathways, [599](#)

Aqueous shunt procedures, [2114](#)

Arbitration grade, [1132](#)

Archer classification, for Wyburn-Mason syndrome, [2453–2454](#),  
[2454t](#)

Archimedes' principle, [1958](#)

Argon laser photocoagulation, for DME, [674](#)

Argus I system, in artificial vision, [2343](#), [2354f](#)

Argus II array, implantation of, [2373–2374](#)

Argus II system, in artificial vision, [2343–2344](#), [2344f](#)

Arms, [198](#)

ARN syndrome, [Acute retinal necrosis syndrome](#)

Arrestin, rhodopsin quenching, [394](#)

Arteriolar attenuation, [1772](#)

Arteriolar bifurcation, retinal macroaneurysms in, [1151](#), [1151f](#)

Arteriovenous malformation, [30f](#)

Artery occlusion, central retinal, [496](#)

Artificial retina, retinitis pigmentosa and, [917](#)

Artificial Silicon Retina (ASR), [2345f](#), [2351–2352](#)

Artificial vision, [2340–2357](#)

background and history of, [2340–2341](#)  
cortical prosthesis for, [2341–2342](#)  
electrotherapeutics for, [2351–2352](#)  
MESE 12 system for, [2344](#), [2345f](#)  
Microfluidic Retinal Prosthesis for, [2351](#)  
optic nerve prosthesis for, [2342](#)  
optogenetics for, [2352–2353](#)  
retinal prosthesis in, [2342–2351](#), [2353f](#)  
    Argus I system in, [2343](#), [2354f](#)  
    Argus II system in, [2343–2344](#), [2344f](#)  
    epiretinal prosthesis in, [2343–2345](#)  
    retinitis pigmentosa in, [2342–2343](#)  
subretinal prosthesis for, [2346–2349](#), [2346f–2347f](#)  
suprachoroidal and transscleral retinal prostheses for, [2349–2351](#),  
    [2352f](#)  
visual prostheses for, [2341–2351](#)

A-scan ultrasonography, [2623](#)

*Ascl1* gene, [380](#)

Aseptic orbital cellulitis, retinoblastoma as, [2391](#)

Asian Americans, prevalence of diabetic retinopathy, [1022](#)

Aspergillosis, [1645](#)

*Aspergillus*

    in endogenous endophthalmitis, [1702–1703](#)  
    infection, case in vitreous biopsy, [2300b](#), [2301f](#)  
    infectious endophthalmitis, [2269](#)

Aspiration, of liquefied blood, [2235](#)

Aspirin, central serous chorioretinopathy and, [1479](#)

ASR, [Artificial Silicon Retina \(ASR\)](#)

Astaxantin, [819–820](#)

Asteroid hyalosis, [277](#), [281f](#)

Astigmatic errors, caused by scleral buckles, [1877](#)

Astigmatism, regressed ROP and, [1256](#)

Astrocytes

- retinal cell types and, [380](#)
- in retinal detachment, [696–697](#), [697f](#)

Astrocytic hamartomas, [2440](#), [2440f–2441f](#)

- differential diagnosis of, [2442–2443](#), [2443b](#)

Astrocytoma, [2653](#)

Asymptomatic retinal breaks, [2021](#)

Ataxia telangiectasia mutated (*ATM*) gene, [1185](#)

Atherosclerosis, ocular ischemic syndrome and, [1227](#)

Atherosclerosis Risk in Communities (ARIC) study, [1021](#)

*Atoh7* gene, [380](#)

Atorvastatin, for ocular ischemic syndrome, [1237](#)

Atrophic age-related macular degeneration, [127f](#)

Atrophy, myopic chorioretinal, [1429](#), [1430f](#)

A-type horizontal cells

- gap junctions between, [420f](#)
- in rabbit retina, [418f](#)

Atypical toxoplasmic retinochoroiditis, [1682](#)

Autoantibodies, [632–633](#)

- PVM and, [2478](#)

Autofluorescence, [22–24](#), [24f](#)

- in autosomal dominant radial drusen, [985](#)

in Best macular dystrophy, 962–963  
choroidal osteoma and, 2634  
circumscribed choroidal hemangioma, 2642  
fundus, 1182–1183, 1184*f*  
    for epiretinal membrane, 2198  
in Stargardt disease, 973–974

Autofluorescence imaging, 120–142  
    basic principles of, 120–121  
        fundus autofluorescence, 120, 120*f*–121*f*, 124*f*–129*f*, 131*f*, 136*f*–

Basepairs, [713](#)

Basic fibroblast growth factor (bFGF), [786](#), [813](#)

- for neuroprotection, [615](#)
- and proliferative vitreoretinopathy, [1859](#)

Basic helix-loop-helix (bHLH), [378](#)

Basigin 1 (BSG1), [818](#)

“BBSome,” gene mutations, [906](#)

B-cell origin, [2660–2661](#)

BCNU (Carmustine), retinal toxicity from, [1727](#)

*Bcor* gene, [376t](#)

BDNF, [Brain-derived neurotrophic factor](#)

BDUMP, [Bilateral diffuse uveal melanocytic proliferation \(BDUMP\)](#)

“Bear tracks”, [2490–2491](#)

“Bear-track” pigmentation, [Grouped pigmentation of retina](#)

Beaver Dam Eye Study, [1180](#), [1376](#)

Benzoporphyrin-derived photosensitizers, [2605](#)

Best corrected visual acuity (BCVA), [673.e1](#)

- greater gain in, [680](#)

Best disease, [Best macular dystrophy](#)

Best macular dystrophy, [955–965](#)

- autofluorescence in, [962–963](#)
- clinical features of, [956–963](#)
- electrophysiology of, [963](#)
- fluorescein angiography in, [962–963](#), [963f](#)
- fundus photograph of, [956f](#), [958f–962f](#)

- genetics in, [963](#)
- histopathology of, [963–964](#), [963f](#)
- optical coherence tomography in, [957–962](#)
- pathophysiology of, [963–964](#), [964f](#)
- refractive error in, [957](#)
- treatment for, [965](#)
- visual function in, [957](#)

*BEST1* gene, [955–956](#), [963](#)

- autosomal dominant vitreoretinopathopathy (ADVIRC) and, [964](#)
- autosomal recessive bestrophinopathy (ARB) and, [965](#)

Beta-carotene, AMD and, [1276](#)

Beta-emitters, [2568](#)

Beta-plus ( $\beta^+$ ) thalassemia, [1203](#)

Bevacizumab

- for age-related macular degeneration, [1381–1382](#)
  - intravenous use of, [1381](#)
  - systemic use of, [1381](#)
- for angioid streaks, [1443](#)
- for branch retinal vein occlusion, [1163](#)
- in Coats disease, [1261](#)
- half-life of, [1381](#)
- for macular edema, [680](#), [1173](#)
- for ocular ischemic syndrome, [1237](#)
- during pregnancy, [1780](#)
- for radiation retinopathy, [1224](#)
- for retinal macroaneurysms, [1152–1153](#)

for TTP, [1241](#)

Bevacizumab Eliminates the Angiogenic Threat for Retinopathy of Prematurity (BEAT-ROP), [1816](#)

bHLH, [Basic helix-loop-helix](#)

Bietti's crystalline dystrophy, [1002–1003](#)

Biguanides (Metformin), for diabetes mellitus, [1056](#)

Bilateral choroidal osteoma, [2628](#), [2630f](#)

Bilateral diffuse uveal melanocytic proliferation (BDUMP), [2481f](#), [2551.e1–2551.e2](#), [2551.e2f](#)  
associated with systemic malignant neoplasms, [2655](#)

Bilateral disease, [1593–1594](#)  
treatment algorithm for, [1593f](#)

Bilateral macular edema, leukemia and, [2662](#)

Bilateral retinoblastoma, [2382–2383](#), [2393](#)

Bimanual dissection, [1970](#)

Binding, rhodopsin quenching, [394](#)

Binding protein/glucose-regulated protein 78 (BIP/GRP78), [597–599](#), [598f](#)

Binocular indirect ophthalmoscope, [143](#)

Biological agents, of sarcoidosis, [1582](#)

Biological consequences, of nanomedicine, [802](#)

Biomimicry, [781](#)

Bionic retina, [794–797](#)

Biopsy  
choroidal, [2303–2305](#)  
fine-needle, [2305–2306](#)  
retinal, [2057](#)  
transvitreal retinal, [2302–2303](#)

vitreous, [2298–2300](#)

Bioptigen SDOIS/Envisu portable system, [167](#), [168f](#)

Bipolar cells, [421f](#)

- blue cones, [424](#)
- cone, [421](#)
  - ON, [422–428](#), [422f](#)
  - OFF, [422](#), [422f–423f](#)

- midget, [424](#)
- rod, [424](#), [425f](#), [427f](#)

, Birdshot chorioretinopathy, [66–71](#), [1516–1520](#)

- clinical course and prognosis of, [1517–1518](#)
- clinical symptoms of, [1517](#)
- differential diagnosis of, [1520](#)
- electrooculogram for, [1519](#)
- electrophysiology of, [1519](#)
- electroretinogram for, [1519](#)
- epidemiology of, [1517](#)
- fluorescein angiography for, [1518](#), [1518f](#)
- fundus autofluorescence for, [1519](#)
- fundus findings in, [1517](#), [1517f](#)
- imaging of, [1518–1519](#)
- immunosuppressive therapy for, [1520](#)
- indocyanine green angiography for, [1518–1519](#), [1518f](#)
- management/treatment of, [1520](#)
- ocular findings in, [1517](#)
- optical coherence tomography for, [1519](#), [1519f](#)

- pathogenesis of, [1520](#)
- systemic associations in, [1520](#)
- visual field testing for, [1519–1520](#)

Birdshot chorioretinopathy, wide-field imaging for, [151f](#)

Black sunbursts, [1209](#), [1209f](#)

*Blastomyces dermatitidis*, infectious endophthalmitis, [2270](#)

Blau syndrome, [Familial juvenile systemic granulomatosis](#)

Blau's disease, [629](#)

Bleb-associated endophthalmitis, [2277](#)

Bloch-Sulzberger syndrome, [Incontinentia pigmenti](#)

Blocked choroidal fluorescence, [14–19](#), [17f](#)

- deep retinal material in, [14–15](#)
- subretinal material in, [15–16](#), [18f–19f](#)
- vascular filling defect in, [16–17](#)
  - choroidal, [18–19](#), [22f–23f](#)
  - of disc, [17](#), [21f](#)
  - retinal, [17](#), [20f–21f](#)

Blocked fluorescence, [12](#)

Blood

- aspiration of liquefied, [2235](#)
- removal of, for SMH, [2235](#)

Blood flow, [183](#)

- assessment of, [183–185](#)

Blood glucose control, proliferative diabetic retinopathy and, [1103](#)

Blood oxygen (O<sub>2</sub>)-carrying capacity, in hypoxia, [490–491](#)

Blood pressure

- AMD and, [1278](#)

diabetic retinopathy, [1026–1028](#)

Blood testing, Coats disease and, [1194](#)

Blood velocity, [183](#)

Blood-borne cells, and proliferative vitreoretinopathy, [1858](#)

Blood-ocular barrier, [656–657](#)

Blood-retinal barriers (BRBs), [628](#), [667](#)

- breakdown of, diabetic retinopathy and, [1040](#)
- components of, [668](#), [669f](#)
- disruption of, [673](#)

Blue cone monochromacy, [256–257](#)

Blue cones, [413](#), [413f](#)

- bipolar cells, [424](#)

Blue Mountain Eye Study, [587–588](#)

Blue reflectance, [127f](#)

Blue-cone monochromacy, [1009–1010](#)

- diagnosis of, [1009–1010](#)
- molecular basis of, [1010](#)
- treatment of, [1010](#)

Blunt trauma, vitreoretinal effects of, [569](#), [570f](#)

Blurred vision, retinal metastases and, [2462](#)

B-mode technique, in ultrasound, [274–275](#), [274f](#)

- choroidal melanoma on, characteristics of, [306–307](#), [307f–310f](#)

*Bmp4* gene, [376t](#)

*Bmp7* gene, [376t](#), [378](#)

Body mass index, diabetic retinopathy studies, [1029](#)

BOLT trial, [680](#)

Bone marrow transplant retinopathy, *versus* radiation retinopathy,

1223

Bone marrow-derived EPCs, potential clinical utility of, [772–773](#), [773f–775f](#)

Bone marrow-derived progenitor cells (BMPC), [493–494](#)

Bone morphogenetic protein, [460t](#)

Bony hypoplasia, of midface, in retinoblastoma, [2407](#)

Bony tumor surface, of choroidal osteoma and, [2628–2629](#), [2629f](#)

Bornholm eye disease, [1010](#)

Boston Retina Implant Project (BRIP), [2348](#), [2348f–2349f](#)

Bourdon tube, [792](#)

Brachytherapy, [2550](#), [2550f–2551f](#), [2614](#)

adjuvant therapy, [2576–2577](#)

for choroidal melanoma, [2566–2581](#)

dosimetry, [2566–2567](#)

indications for treatment, [2569–2571](#)

juxtapapillary tumors, [2571](#)

large tumors, [2570](#)

medium tumors, [2569](#)

small tumors, [2569–2570](#)

isotope selection, [2567–2568](#), [2567f–2568f](#), [2567t](#)

physical characteristics of used isotopes for, [2567t](#)

plaque design, [2568–2569](#), [2568f–2569f](#)

plaque placement technique, [2571–2573](#), [2572f](#)

local tumor response, [2573–2574](#)

plaques, choroidal metastases and, [2624](#)

radiation complications and, [2574–2575](#)

radiation-related complications, management of, [2575–2576](#)

- anti-VEGF, [2575–2576](#)
- corticosteroids, [2576](#)
- laser photocoagulation, [2576](#)
- recurrences, [2574](#)
- for retinoblastoma, [2400–2401](#), [2401f–2402f](#)
- for uveal melanoma, [1775](#)
- visual outcomes and, [2574–2575](#)

Bradykinin, diabetic retinopathy and, [1040](#)

Brain tumors, TSC and, [2439](#)

Brain-derived neurotrophic factor (BDNF), [384](#), [460t](#), [812–813](#)

Brainstem, [1591t](#)

Branch retinal artery occlusion, [20f](#), [101–102](#), [102f](#), [1143](#), [1143f](#), [1628](#)

Branch retinal vein occlusion (BRVO), [357f](#), [358](#), [359f](#), [680](#), [1155–1165](#)

- acute, [1156](#), [1156f](#)
- chronic, [1156](#), [1157f](#)
- clinical evaluation of, [1157–1159](#)
- clinical examination of, [1157–1158](#)
- clinical features of, [1156](#)
- complications of, [1156](#)
- diagnostic workup of, [1158–1159](#)
- fluorescein angiography of, [1157](#), [1158f](#)
- follow-up for, [1163](#)
- natural history of, [1156–1157](#)
- in older patient, [1159](#)
- optical coherence tomography of, [1158](#), [1159f](#)
- pathogenesis of, [1155–1156](#)
- risk factors of, [1155](#)

- signs of, [1156](#)
- symptoms of, [1156](#)
- treatment options for, [1159–1163](#)
  - of macular edema, [1161–1163](#)
  - of underlying etiology, [1159–1160](#)
  - of vision-limiting complications, [1160–1161](#)
- wide-field angiography of, [1158](#), [1158f](#)
- in young patient, [1158–1159](#)

Branch vein occlusion, [36f](#)

Branch Vein Occlusion Study (BVOS), [1802](#)

BRAVO Investigators, clinical trials of, [1803](#)

Break localization, in scleral buckling surgery, [1894](#), [1894f–1895f](#)

Bright flash mixed rod-cone ERG, [250–255](#), [251f](#)

- extinct type of, [255](#)
- negative type of, [251–255](#)
  - diagnostic value in, [254–255](#)
  - prognostic value in, [251–254](#), [253f–256f](#)
- normal type of, [251](#), [252f](#)
- selectively abnormal oscillatory potentials in, [251](#), [252f](#)
- subnormal type of, [251](#), [253f](#)

Bright lesions, [209](#)

Brilliant blue

- macular hole and, [2222](#)
- subretinal injection of, [2370](#)

Brilliant blue G dye, [362](#)

Brimonidine, [786](#)

- for age-related macular degeneration, [1412–1413](#)

BRIP, [Boston Retina Implant Project \(BRIP\)](#)

British N system, [342](#)

British Ophthalmological Surveillance Unit, [1710–1711](#)

Cell-based replacement therapy, stem cells in, [2311–2312](#)

Cell-by-cell dose delivery and control, [802](#)

, Cellophane maculopathy, [2194](#)

Cells

- amacrine, [428–434](#), [428f](#)
  - dopaminergic, [432–433](#), [433f](#)
  - S1 and S2, [430–432](#), [430f](#)
  - starburst, [433–434](#), [434f](#)
- bipolar, [421f](#)
  - blue cones, [424](#)
  - cone, [421](#)
  - horizontal and, [417–418](#)
  - midget, [424](#)
  - rod, [424](#), [425f](#), [427f](#)
- B-type horizontal, [417](#)
- ganglion, [434–439](#)
  - clinical relevance of functional anatomy, [440–441](#), [442f](#)
  - color vision and, [439](#)
  - for control of pupil diameter and circadian rhythm, [438–439](#)
  - dye-injected, in rabbit retina, [436f](#)
  - new tools to identify, [439–440](#)

ON/OFF directional selective, [437f](#)  
visual channel in, [435–438](#)  
midset bipolar, [424](#)  
transfection of, [835](#), [835f](#)

Cellular cords, medulloepithelioma and, [2652–2653](#)

Cellular replacement, in retina, [617–618](#)

Cellular responses, modeling of, [228](#)

Cellular therapy, [763–779](#)  
adult bone marrow-derived endothelial progenitor cells, [772–773](#)  
definitions of, [763–765](#)  
discerning legitimacy of human stem cell treatment, [775](#)  
human clinical trials using stem cells for treatment of retinal disease, [773–775](#)  
retinal pigment epithelium (RPE) cells, [767–772](#)  
retinal stem and Müller glial cells, [765–767](#)

Central areolar choroidal dystrophy, [980f](#), [981](#), [997–998](#), [998f](#)

Central areolar retinochoroidal dystrophy, [981](#)

Central dogma of DNA, [713](#)

Central nervous system (CNS), [409](#), [1696](#)  
findings, of primary vitreoretinal lymphoma (PVRL), [2676–2677](#)  
involvement, of primary vitreoretinal lymphoma (PVRL), [2678](#)  
treatment, of primary vitreoretinal lymphoma (PVRL), [2678–2679](#)

Central retina, [417](#)

Central retinal artery, in fundus, [9–10](#)

Central retinal artery occlusion (CRAO), [100](#), [102f](#), [1136–1142](#)  
ancillary studies of, [1139](#)  
clinical features of, [1136–1139](#), [1137f–1139f](#)  
epidemiology of, [1136](#)  
evaluation of, [1140–1141](#)  
in lymphoma, [2667](#), [2668f](#)  
in optic disc drusen, [1789](#)  
systemic associations of, [1139–1140](#), [1141b](#)  
treatment for, [1142](#)

Central retinal vein, [1666](#)

Central retinal vein and branch retinal vein occlusion (CRVO/BRVO), spectral imaging and, [188](#)

Central retinal vein obstruction, [2665](#), [2665f](#)

Central retinal vein occlusion, [1576](#), [1628](#)

Central Retinal Vein Occlusion (CRUISE) trial, [1172](#)

Central retinal vein occlusion (CRVO), [348](#), [349f–350f](#), [1144–1145](#), [1166–1179](#)  
cilioretinal artery occlusion and, [1143](#)  
clinical evaluation of, [1169–1170](#)  
clinical features of, [1166–1168](#), [1166f–1168f](#)  
introduction to, [1166](#)

laboratory workup for, 1170*b*  
in optic disc drusen, 1789  
from oral contraceptives, 1729, 1729*f*  
pathogenesis of, 1168–1169  
perfusion status of, 1168  
risk factors and associations of, 1169, 1169*b*  
therapeutic options for, 1170–1175, 1170*f*, 1171*t*  
    alternative treatments aimed at underlying etiology as, 1174–1175  
    definitive treatment of ocular neovascularization, 1174  
    follow-up in, 1175–1176  
    macular edema, treatment of, 1170–1174  
    medical therapy, 1174  
    surgical treatments as, 1175  
    systemic medical conditions, treatment of, 1174  
wide-field imaging for, 148, 149*f*–150*f*

Central scotoma, 359, 360*f*

Central serous chorioretinopathy (CSC), 38*f*, 59, 63*f*–64*f*, 94–97, 138, 140*f*, 706–707  
    acute, 94, 96*f*  
    chronic, 94, 96*f*  
    enhanced-depth imaging OCT in, 97, 97*f*  
    nonrhegmatogenous retinal detachment in, 1828–1830  
    in pregnancy, 1773  
    wide-field imaging for, 161, 161*f*

Central serous chorioretinopathy (CSCR), 1465–1483  
    acute, 1475–1476  
    age-related macular degeneration, 1467

ancillary testing of, [1468–1474](#)  
anti-vascular growth factor (VEGF) injections, [1478](#)  
autoimmune and vascular disorders, [1468](#)  
clinical features of, [1466–1467](#)  
definition of, [1465](#)

Choriocapillaris endothelial basement membranes, RPE and, [455](#)

Chorioretinal anastomosis (CRA), [57f](#), [1174](#), [1354](#)

Chorioretinal atrophy, [71–73](#)  
myopic, [1429](#), [1430f](#)

Chorioretinal biopsy, for diagnostic vitrectomy, [2289](#)

Chorioretinal folds, idiopathic, in hypotony maculopathy, [1492](#)

Chorioretinal scars, in ocular histoplasmosis, [1447f](#)

Chorioretinopathy  
birdshot, wide-field imaging for, [151f](#)  
central serous, during pregnancy, [1773](#)

Choriovaginal vessels, [53f](#)

Chorista, [2446–2447](#)

Choristoma, [2446–2447](#)

Choroid  
age-related macular degeneration and, [1297](#), [1298f](#)  
atrophy, [Central areolar choroidal dystrophy](#); [Diffuse choroidal dystrophy](#); [Gyrate atrophy](#); [Peripapillary choroidal dystrophy](#)  
changes to, [1323–1324](#)  
early AMD and, [1285–1286](#)  
hypotony, ocular layers due to, changes in, [302](#), [304f–305f](#)  
melanoma in, [306–314](#)  
on A-mode ultrasonography, [307](#), [307f](#), [311f](#)  
on B-mode echography, [306–307](#), [307f–310f](#)  
treatment of, role of ultrasonography for, [308–314](#), [313f–315f](#)

- volume of, by ultrasonography, [307–308](#), [312f](#)
- metastatic tumors in, [314–316](#), [315f–316f](#)
- neovascularization in, [286f](#), [302](#), [306f](#)
- as neuroprotective agent, [615t](#)
- pathologic myopia and, [1424–1425](#), [1425f](#)
- tuberculoma in, [316](#), [319f](#)
- ultrasound of, [302–316](#)
- uveal effusion syndrome in, [316](#), [320f](#)

Choroid graft transplantation, visual acuity after, [2261f](#)

Choroid translocation

- in age-related macular degeneration, [2254–2265](#)
- retinal pigment epithelium and stem cells, [2261–2263](#)

Choroidal angiogenesis, retinal and, [638–655](#)

- impact of, [638–640](#)
- mechanisms of, [643–645](#), [644f](#)
  - AMD, [645](#)
  - Bruch's membrane, enzymatic and mechanical disruption of, [643–645](#)
  - choroidal neovascularization (CNV), [645](#)
  - complement factor H (CFH), [645](#)
  - drusen, basal laminar/linear deposit formation, [643](#)
  - macrophages, [645](#)
  - microglial cells, [645](#)
  - retinal pigment epithelium, aging and senescence of, [643](#)

neovascularization and, [638](#), [639f](#)

- angiogenic factors in, [645–648](#)
- antiangiogenic factors in, [645–648](#)

- associated with retinopathy of prematurity, [642–643](#)
- in diabetes, [640–642](#)
- other factors in, [647–648](#)
- in uveitis, [643](#)
- in vascular occlusions, [642](#)
- normal retinal vascular development in, [640](#)
- pathogenesis of, [640](#)
- Choroidal atrophy, [23f](#)
- Choroidal biopsy, [2303–2305](#)
  - case studies, [2305b](#), [2305f](#)
  - for diagnostic vitrectomy, [2289](#)
  - histologic technique, [2305](#)
  - results, [2305](#)
  - surgical technique, [2304–2305](#)
    - transscleral biopsy, [2304–2305](#), [2304f](#)
    - transvitreal biopsy, [2304](#)
- Choroidal blood flow, increase in, for age-related macular degeneration, [1411](#)
- Choroidal circulation, in fluorescein angiography, [9](#)
- Choroidal coloboma, retinal detachments associated with, [1980](#)
- Choroidal diseases, hereditary, [997–1005](#)
- Choroidal disorders, in pregnancy, [1771–1776](#)
  - and preeclampsia, eclampsia, and “HELLP” syndrome, [1771](#)
- Choroidal dysfunction, [1772](#)
  - etiology of, [1772](#)
- Choroidal dystrophy, [997](#)
  - wide-field imaging for, [157–159](#), [157f–158f](#)

Choroidal effusion syndrome, [705](#), [708](#)

Choroidal fluorescence, [10](#), [12](#)

Choroidal hemangioma, [59–61](#), [1779](#), [2451](#)

- abnormal choroidal vessels in, [33f](#)
- cavernous type of, [2643f](#)

Conventional therapy, for diabetes, [1024](#), [1024t](#)

Convolutional Neural Networks, [204](#)

COPERNICUS Study, clinical trials of, [1803](#)

COPERNICUS trial, [1173](#)

Copper supplement, AMD and, [1276](#)

Copy number variants (CNVs), [717](#)

Coralline hydroxyapatite (HA), [2562](#)

Cornea

- keratoprosthesis and, pediatric vitreoretinal surgery and, [2173](#), [2173t](#)
- in UBM, [275](#)

Corneal decompensation, [1967](#)

Corneal edema, proliferative diabetic retinopathy and, [2122](#)

Corneal hysteresis, [1880](#)

Corneal lesions, [1576](#)

Corneal toxicity, heavy tamponade and, [1992–1993](#)

Corneal transplantation, postoperative infection endophthalmitis, [2272](#)

Coronary heart disease, hypertensive retinopathy and, [1124](#)

Cortical blindness, [1773](#)

Cortical prosthesis, for artificial vision, [2341–2342](#)

Cortical tubers, [2439f](#)

Cortical vision loss, [1773](#)

Corticosteroids, [2576](#)

- in Coats disease, [1197](#)
- intravitreal, [1705](#)
- for ITP, [1241](#)
- , for macular edema, [677–679](#), [678f](#), [1172](#)
- ocular complications of, [1617–1618](#)
- for ocular trauma, [1871](#)
- pharmacotherapy with, [1079–1081](#)
- preparations, retinal toxicity from, [1726–1727](#), [1728f](#)
- proliferative vitreoretinopathy and, [1995](#), [1995f](#)
- for radiation retinopathy, [1224](#)
- for serpiginous choroiditis, [1529](#)
- for sympathetic ophthalmia, [1501](#)
- for Vogt-Koyanagi-Harada disease, [1512](#)

*Corynebacterium diphtheriae*, infectious endophthalmitis, [2268](#)

Cost-effectiveness, of telemedicine for ROP, [1270](#)

Cotton-wool spots, [1145–1147](#), [1145f–1146f](#), [1146b](#), [1241–1243](#), [2664–2665](#), [2664f](#)

- epiretinal membrane with, [2195](#), [2196f](#)
- in NPDR, [1066f](#), [1068–1069](#), [1069f](#)
- in ocular ischemic syndrome, [1231](#), [1231.e1f](#)

Counseling, in patient, [2558](#)

Coupling diagnostics, nanomedicine and, [792](#), [793f](#)

C-peptide, status in diabetic retinopathy, [1026](#)

CpG dinucleotide, [734](#)

Cray XT5 supercomputer, [781](#)

*CRB1* gene, [376t](#)

- mutation in, [1189](#)

CRD, [Cone-rod dystrophy \(CRD\)](#)

*Crocus sativus*, [818–819](#)

Crowdsourcing, diabetic retinopathy grading and, [1132](#)

CRUISE Investigators, on vein occlusion, [1804](#)

CRVO, [Central retinal vein occlusion \(CRVO\)](#)

*Crx* gene, [376t](#), [383](#)

*Crx*-expressing cells, [2323–2324](#)

Cryopexy

- in pneumatic retinopexy, [1946](#)
- prophylactic, snowflake vitreoretinal degeneration and, [939](#)

Cryotherapy, [1895–1896](#), [1895f–1897f](#)

- for Coats disease, [1196–1197](#), [1198f](#)
- for extrapapillary retinal hemangioblastomas, [2433](#)
- for prevention of retinal detachment, [2026](#)

for retinal detachment, [2013](#)  
in retinal surgeries, [1958](#)  
for retinoblastoma, [2398–2399](#)  
in ROP, [1258–1259](#)

Cryotherapy for Retinopathy of Prematurity (CRYO-ROP)  
Multicenter Trial of, [1814–1816](#)  
study, [1259](#)

*Cryptococcus neoformans*, [1644](#)  
in endogenous endophthalmitis, [1703](#)

Crystalline dots, macular telangiectasia and, [1181](#), [1182f](#)

Crystalline lens, [1746](#)

Crystalline retinopathy, from drug toxicity, [1734–1738](#)

CSC, [Central serous chorioretinopathy \(CSC\)](#)

CSCR, [Central serous chorioretinopathy \(CSCR\)](#)

CSNB, [Congenital stationary night blindness \(CSNB\)](#)

CT scanning, in retinoblastoma, [2390](#)

*CTC1* gene, mutation in, [1189](#)

Curcumin, [590](#)

Curie brothers, in ultrasound, [273](#)

Current source density (CSD), [227](#)

Cut down techniques, in subretinal fluid drainage, [1905](#), [1905f](#),  
[1905.e1f](#)

Cutaneous melanoma, [2533–2535](#)

Cutaneous nevi, [2517](#)

“Cuticular drusen”, [87](#)

C-wave, [228–229](#), [230f–231f](#)

CX3CL1, [670](#)

Cyanoacrylate tissue glue, [2305](#)

Cyclic adenosine monophosphate (cAMP), retinal adhesion and, [512](#), [513f](#)

Cyclin dependent kinase inhibitors (CDKIs), [2381](#)

“Cyclitic membranes,” in chronic retinal detachment, [295](#), [297f](#)

Cyclodestructive therapy, proliferative diabetic retinopathy and, [2115](#)

Cyclosporine

- for sympathetic ophthalmia, [1501–1502](#)
- for Vogt-Koyanagi-Harada disease, [1512](#)

Cystic retinal tuft, [560f](#)

Cysticercosis, [1696–1697](#)

Cystoid macular edema (CME), [35f](#), [58f](#), [97–98](#), [98f](#), [865](#), [911](#), [1586–1587](#), [1641](#), [2576](#)

- anomalous posterior vitreous detachment, [565](#), [566f](#)
- blood-retinal barrier in, [657](#)
- circumscribed choroidal hemangioma, [2638](#)
- classic pattern of, [667](#), [668.e1f](#)
- complication in macular translocation, [2248–2250](#)
- from drug toxicity, [1732–1734](#)
- in epiretinal membrane, [2195](#), [2196f](#)
- focal ERG and, [263](#), [265f](#)
- retinal nuclear receptor (NR2E3)-related diseases and, [947](#)
- vitreoretinal traction and, [2200–2206](#)
  - anatomy of, [2200](#)
  - clinical entities associated with, [2203–2206](#)
  - clinical signs of, [2201](#)
  - imaging of, [2201–2202](#)

- pathophysiology of, [2200–2201](#)
- surgical treatment for, [2202–2203](#)
- in X-linked retinoschisis, [945](#)

Cystoid retinal edema, [36f](#)

Cysts, in macula, [361–362](#)

Cytochalasin B, retinal adhesion and, [510](#)

Cytochrome C oxidase deficiency, [727t](#)

Cytokine-mediated inflammation, and proliferative vitreoretinopathy, [1859](#)

Cytokines, [632–633](#), [1858](#)

- exudative AMD and, [1376–1381](#)
- inflammatory, [670](#)
- rapid clearance of, [682](#)
- Vogt-Koyanagi-Harada disease and, [1511f](#)

Cytologic features, [2542–2543](#), [2544f](#)

CytoLyt®, [2677](#)

Cytomegalovirus (CMV), [2666](#)

- in ARN syndrome, [1712](#)
- ocular syphilis *vs.*, [1674t](#)

Cytomegalovirus (CMV) retinitis, [1628–1641](#), [2468](#), [2468f](#), [2666f](#)

- active
  - with no systemic treatment, [1637f](#)
  - with systemic ganciclovir, [1640f](#)
- active peripheral, [1632f](#)
- complications of, [1641](#)
- culture-positive for, [1630](#)
- entoptic perimetry for, [1631f](#)

fluorescein angiogram of, [1629f](#)  
in HAART era, [1640–1641](#)  
intraocular therapy of viral retinitis, [1635–1638](#)  
pathogenesis, diagnosis, and clinical manifestations, [1628–1630](#),  
[1628f](#), [1630f](#)  
reactivation of, [1628–1629](#)  
resistance, [1634](#)  
rhegmatogenous retinal detachment and, [1638–1640](#), [1638f–1639f](#),  
[2140f–2142f](#), [2141–2142](#)  
screening techniques for retinal and systemic CMV infection,  
[1630–1631](#)  
silicone oil (SO) and, [1980](#)  
smoldering, [1630f](#)  
summary of, initial systemic treatment, [1635](#)  
systemic therapy of, [1631–1635](#)  
treatment of, [1631](#)  
wide-field imaging for, [148–149](#), [153f–154f](#)

Cytomegalovirus-cystic fibrosis transmembrane conductance  
regulator (CMV-CFTR), [789](#)

Cytoskeleton, RPE and, [455](#)

Cytotoxic edema, [Intracellular edema](#)

## D

DA VINCI study, treatment trials of, [1800](#)  
DACE (drain, air, cryotherapy, explant), [1894](#), [1895f](#)  
“Dalen-Fuchs-like” granulomas, [1576](#)  
Daptomycin, for endogenous endophthalmitis, [1703–1704](#)  
Dark adaptation

clinical evaluation, [328](#)  
functions of, [328](#), [328f](#)

Dark adaptometry, retinitis pigmentosa and, [873](#), [876f](#)

Dark atrophy, [71](#)

“Dark without pressure” lesions, in SCD, [1206](#)

Dark-adapted (scotopic) ERGs, [225f](#), [226](#)

DARPs, [1402–1403](#)

Data and Safety Monitoring Committee, [2615](#)

Daunorubicin, proliferative vitreoretinopathy and, [1996–1997](#)

Deacetylation, [734](#)

“Dead” retinas, generic strategies for reversing blindness in, [758](#)

Deafness, maternally inherited diabetes and, [989](#), [989f](#)

Death, systemic prognosis for, [2524–2525](#)

Deep retinal material, in blocked choroidal fluorescence, [14–15](#)

Deep scleral incision, [2592](#), [2593f–2594f](#)

Deep sequencing, [720](#)

Deeper chorioretinal lesions, [1576](#)

Deep-learning, [202](#)

Deferoxamine, retinal toxicity from, [1726](#), [1727f](#)

Degeneration, age-related macular, [1293–1344](#)  
Age-Related Eye Disease Study, [1334–1336](#), [1335f](#), [1335t–1336t](#)  
basal laminar deposits, [1299–1300](#), [1300f–1303f](#)  
basal linear deposits, [1300](#), [1300f](#), [1302f–1303f](#)  
Bruch's membrane, [1296–1297](#)  
cataract surgery and, [1337](#)  
, drusen  
    clinicopathologic characteristics of, [1306–1310](#), [1308f](#)

- histochemistry of, 1315
- histopathology of, 1310–1312
- imaging of, 1312–1315
- on fundus imaging, 1297, 1299*f*
- membranous debris, 1300*f*, 1301, 1303*f*–1305*f*
- non-neovascular
  - future directions for management of, 1339–1340
  - histologic alterations of, 1298–1304
  - pathology of, 1297–1328
  - visual impairment from, 1337–1339
- prognosis and management of, 1328–1340
- risk of, anatomic progression in, 1329–1330, 1329*f*, 1330*t*

Degenerative changes, 2546, 2548*f*

Degenerative retinoschisis, 945, 1850–1855

- definitions and pathology of, 1850, 1850*f*
- and progressive rhegmatogenous retinal detachment, 1853–1855, 1854*f*
- and retinoschisis, 1850–1852, 1851*f*–1852*f*, 1851*t*
  - with retinal breaks, 1852–1853, 1852*f*
- schisis-detachment and, 1853

Dementia, hypertension and, 1125

Dendrimer glucosamine, 784–785

Dendrimer glucosamine 6-sulfate, 784–785

Dendrimeric polyguanidilyated translocators (DPT), 784

Dendrimers, 783–784

Densiron 68, 1990

Deoxyribonucleic acid (DNA), 713–714

- transfection efficiency of, [834](#)
- Depo-Medrol, [1726–1727](#)
- Depot placement, impact of, [840](#)
- Depth-dose curve, [2582f](#)
- Depth-doses of radiation, [2567f](#)
- Dermatomyositis, [1611–1612](#)
  - articular and systemic disease of, [1611](#)
  - epidemiology of, [1611](#), [1611b](#)
  - ocular disease of, [1611](#)
  - treatment of, [1611–1612](#)
    - of ocular disease, [1612](#)
    - of systemic disease, [1611–1612](#)
- Detachment of the retinal pigment epithelium (PED), [1285](#)
- Detection, in retinal image analysis, [203](#)
- Deutan, [331](#)
- Deuteranope, [331](#)
- “Deviant” systemic immune response, antigen-specific, induction of, [2317](#)
- Devices, drug delivery and, [834](#), [836–837](#)
- Dexamethasone
  - in Coats disease, [1197](#)
  - DDS study, treatment trials of, [1800–1802](#)
  - implant, for branch retinal vein occlusion, [1162](#)
  - for macular edema, [679](#), [679.e1f](#)
  - for radiation retinopathy, [1224](#)
  - therapy, in RPE transplantation, [2319–2320](#)
- Dexamethasone intravitreal implant (DEX), [679](#)

Dexamethasone intravitreal insert (Ozurdex), [1592–1593](#)

D-EYE system, [177](#)

DHA, [Docosahexaenoic acid supplements \(DHA\)](#)

Diabetes

AMD and, [1278](#)

bone marrow-derived progenitor cells and, [494–495](#)

control of, [2122](#)

conventional therapy for, [1024](#), [1024t](#)

development and progression of long-term complications of, [1024](#), [1024t](#)

duration of, [1023](#), [1023f](#)

  - techniques in, [2199](#)
  - use of vital dyes, [2199](#)
  - when to offer, [2198–2199](#)
- visual field and, [361–362](#)

Epiretinal Membrane Scanning laser ophthalmoscopy (SLO),  
microperimetry, [361f](#)

Epiretinal proliferation  
    diabetic macular edema and, [1072](#), [1073f–1074f](#)  
    in prophylactic therapy, [2029](#)

Epiretinal prosthesis, for artificial vision, [2343–2345](#)

Episcleritis  
    in ARN syndrome, [1710f](#)  
    in rheumatoid disease, [1598](#)

Epithelial growth factor [EGF]-containing fibulin-like extracellular matrix protein 1 (*EFEMP1*), [603](#)

Epithelial-mesenchymal transition, and proliferative vitreoretinopathy, [1857](#)

Epithelioid cells, [2543](#), [2544f](#)

Epithelioid nevus cells, [2506](#)

EPO, [Erythropoietin](#)

Epstein-Barr virus (EBV)  
    in ARN syndrome, [1712](#)  
    infection, [2676](#)

Equator-plus fundus camera, [144](#)

Equilibration, gas resorption and, [1960](#)

ER, [Endoplasmic reticulum \(ER\)](#)

Er: YAG laser, [855](#), [856f](#)

ER-associated degradation (ERAD), [599](#)

Ergot alkaloids, retinal vasoconstriction from, [1730–1732](#)

ERM, [Epiretinal membrane \(ERM\)](#)

Erosive vitreoretinopathy (ERVR)  
    differential diagnosis of, [943](#)  
    ocular features of, [946](#)  
    overview of, [939](#)

Error-prone polymerase chain reaction, [781](#), [790](#)

Erythrocytes

- state of oxygenation in, [1204](#)
- in vitreous hemorrhages, [280](#), [284f](#)

Erythropoietin (EPO), [460t](#), [642](#), [670–671](#)

- hypoxia and, [492](#)

ESCS, [Enhanced S-Cone Syndrome \(ESCS\)](#)

Estradiol, [818](#)

Etanercept, [1594](#)

Ethambutol, [1662t](#)

Ethnicity, CRVO and, [1169b](#)

Ethoxzolamide, retinal folds from, [1734](#)

Evanescient white-dot syndrome, multiple, [366](#)

Evolution, [716](#)

Examination under anesthesia (EUA), staging, in retinoblastoma, [2391–2392](#), [2391f–2392f](#)

Excipients, [833](#)

Excitation, range of, [123f](#)

EXCITE study, for ranibizumab, [1384](#), [1385f](#)

Exenatide, for diabetes mellitus, [1058](#)

Exogenous insulin, impact on diabetic retinopathy, [1026](#)

Exogenous systemic melatonin, [821](#)

Exophytic tumors, [2440–2441](#)

Expansion, gas resorption and, [1960](#)

Experimental autoimmune uveitis (EAU), [628](#)

Experimental autoimmune uveoretinitis (EAU), [660](#), [660t](#), [786–789](#)

Explant, scleral, [1897–1899](#), [1897f–1901f](#)

## Exposure

in choroidal melanoma, [2592](#), [2593f–2594f](#)

rate constant, [2568](#)

## Expressivity, [2378–2379](#)

## Extensional viscosity, [1978](#)

## External beam radiotherapy (EBR)

circumscribed choroidal hemangioma, [2644](#)

for primary vitreoretinal lymphoma (PVRL), [2678](#), [2679f](#)

for retinoblastoma, [2399–2400](#), [2399f–2400f](#)

## Extracellular edema, [668](#)

## Extracellular matrix (ECM), [452](#), [798](#)

degradation of, [455–456](#)

in wound healing and traumatic proliferative vitreoretinopathy, [1870](#)

## Extracellular space (ECS), [224](#)

## Extrafoveal neovascular lesions, laser therapy for, [854](#)

## Extraocular extension, [2595](#)

## Extraocular muscle

of eye, in scleral buckling surgery, [1890](#), [1890f](#)

surgery, for MTS360, [2244](#)

Eckardt technique, for extraocular muscle surgery, [2244](#), [2244f](#)

Freedman technique, for extraocular muscle surgery, [2244](#), [2245f](#)

## Extraocular retinoblastoma, chemotherapy for, [2393](#)

## Extrapapillary retinal hemangioblastomas

ablative treatment of, [2432–2434](#), [2434f](#)

surgical excision of, [2434](#)

## Extrapulmonary lesions, sarcoidosis and, [1573](#)

Extrapulmonary tuberculosis, [1657](#)

Extrascleral extension, of tumor, [2528](#)

Extravasation

- in fluorescein injection, [3](#)
- retinal metastases and, [2462](#)

Extremely asymmetrical retinitis pigmentosa, [885](#), [887f–888f](#)

Extrusion/infection, scleral buckling surgery and, [1911–1913](#)

Exudative age-related macular degeneration, [48–56](#)

- alternative treatments for, [2254](#)
- results in, [2258](#)

Exudative retinal detachment, [707](#), [1825](#), [1825f](#), [2605](#)

- postsurgical, [1845–1847](#), [1846f](#)

Eye, [656](#)

- aged, Bruch's membrane in, [524–527](#)
  - lipid accumulation, [524–527](#), [525f–526f](#)
  - other aging changes, [524t](#), [527](#)
- as an immune-privileged site, [659–662](#), [659t](#)
- closure, [2593f–2594f](#), [2595](#)
- coats of, in scleral buckling surgery, [1889–1890](#), [1889f](#)
- examination, in ROP, [1258](#)
- factors affecting salvage of, in retinoblastoma, [2387–2388](#)
- optical properties of, [844–845](#)
- retinal health and disease and, [625](#)
- tuberous sclerosis and, [2438–2445](#)
- uveal melanoma and, [2518](#)

Eye Disease Case Control Study (EDCCS), [1275](#)

Eye drops, [839–840](#)

Eye field, [377f](#)  
Eye field transcription factors (EFTFs), development role, [376](#)  
Eye surgery, ERG monitoring during, [265](#), [268f](#)  
EyeGate Pharma®, [837](#), [837f](#)  
Eyeless, [376](#)  
Eyelets, [2568–2569](#)  
, Eyelid involvement, of type 1 neurofibromatosis, [2447](#)  
Eylea, [680](#)

## F

FA, [Fluorescein angiography \(FA\)](#)  
Facedown posturing, [1965–1966](#)  
Factor D, [1410–1411](#)  
Factor V Leiden mutation, branch retinal vein occlusion and, [1155](#)  
Factor-inhibiting hypoxia-inducible factor-1 (FIH-1), [491](#)  
FAF, [Fundus autofluorescence \(FAF\)](#)  
FAME study group, treatment trials of, [1801](#)  
Familial adenomatous polyposis (FAP)  
    CHRPE and, [2490](#)  
    prognosis and management of, [2493–2494](#), [2493f](#)  
Familial dominant drusen, wide-field imaging for, [157f](#)  
Familial exudative vitreoretinopathy (FEVR), [1263](#), [1690](#)  
    Coats disease and, [1189](#)  
    pediatric vitreoretinal surgery for, [2183–2185](#), [2184f](#)  
    wide-field imaging for, [155](#), [155f](#)  
Familial juvenile systemic granulomatosis, [1609–1610](#)  
    articular and systemic disease of, [1610](#)

epidemiology of, [1610](#)  
ocular disease of, [1610](#)  
treatment of, [1610](#)  
    of ocular disease, [1610](#)  
    of systemic disease, [1610](#)

Farnsworth- Munsell 100-hue test, [333](#), [333f–334f](#)

Fas Ligand (FasL), [672](#)  
    expression, [628](#)

Fast oscillation trough (FOT), [228–231](#), [230f](#)

Fatigue failure, vitreoretinal surgery and, [1917](#)

Fatty acid, composition of, Bruch's membrane lipoproteins, [526](#)

“Featureless fundus”, [1093](#), [1093f](#)

Feedback mechanism, ephaptic, [418](#)

Feline retina, [689](#)

Femtosecond laser, [782](#)

Fenestrated sheen macular dystrophy (FSMD), [988](#), [988f](#)

Fenestration, for optic pit maculopathy, [2056](#)

Fenofibrate Intervention and Event Lowering in Diabetes (FIELD), [1028](#)

Fenretinide, for age-related macular degeneration, [1410](#)

Fetal tissues, in RPE transplantation, [2310](#)

Fetal toxoplasmosis, [1681](#)

Feulgen stained sections, [2543](#)

FGF, [Fibroblast growth factor](#)

Fibrillins, in vitreous, [544](#)

Fibrin  
    formation, DIC and, [1240](#)

postoperative, retinectomy and, [2069](#)

Fibrinoid syndrome, proliferative diabetic retinopathy and, [2123–2124](#)

Fibroblast growth factor (FGF), [460t](#)

- in angiogenesis, [2462](#)
- in neural retina, [378](#)

Fibroblast growth factor-2 (FGF-2), [646](#)

Fibroblastic proliferation, in ocular trauma, [1868–1869, 1869f](#)

Fibroglial membrane, gray, in optic disc pits, [1791, 1791f](#)

Fibrous proliferation

- extensive periretinal, retinectomy and, [2063](#)
- retinectomy and, [2069](#)

Fibrovascular pigment epithelium detachment (PED), [54f](#)

Fibrovascular proliferations, proliferative diabetic retinopathy and, [2108, 2108f](#)

Fibrovascular retinal pigmented epithelium detachment, [91, 91f](#)

Field potential, [224](#)

Fine-needle aspiration biopsy (FNAB), [2543f](#)

- choroidal metastases and, [2623](#)
- in retinal metastases, [2470](#)
- in retinoblastoma, [2392](#)

Fine-needle biopsy, [2305–2306](#)

- results, [2306, 2306f](#)
- surgical technique, [2305, 2305f](#)

Fingolimod, cystoid macular edema from, [1734](#)

Fish eggs

- formation, [1964](#)
- pneumatic retinopexy and, [1949, 1950f](#)

Flapover approach, surgery for age-related macular degeneration, [2256–2257](#)

Flash photography, in leukocoria, [2388](#)

Flash system, [47](#)

Flecks, in Stargardt disease, [965](#)

Flexible cannulas, [1926](#)

Floater, retinal metastases and, [2462](#)

FLT-1 (FMS-like tyrosine kinase), [1377](#)

Fluconazole

- for endogenous endophthalmitis, [1704](#), [1704b](#)
- intravitreal, [1704](#)

Fluid movement, and scleral buckles, [1885–1886](#), [1886f–1887f](#)

Fluid-air exchange, of vitreoretinal surgery, [1927](#), [1927f](#)

Fluidics, [1919](#)

Fluocinolone, for macular edema, [678–679](#)

Fluocinolone acetonide, [1593f](#)

Fluorescein

- in blocked fluorescence, [12](#)
- filters, [3](#)
- imaging of drusen and, [1312–1314](#)
- injection, [6](#), [6.e1f](#)
  - side-effects and complications of, [3b](#)
- solution, [3–4](#)
- use of, during pregnancy, [1779–1780](#)

Fluorescein angiographic study, [53f–54f](#), [56](#), [56f](#), [58f–59f](#), [61f–65f](#), [67f–69f](#), [71f–72f](#)

Fluorescein angiography (FA), [1–45](#), [44b](#), [176](#), [178f](#), [197](#), [1349–1357](#)

- abnormal, [12–43](#), [13f](#)

for acute posterior multifocal placoid pigment epitheliopathy, 1522, 1522*f*–1523*f*

for acute zonal occult outer retinopathy, 1547, 1548*f*

ancillary testing with, 1563–1564

of angioid streaks, 1439, 1441*f*

in autosomal dominant radial drusen, 985

auxiliary equipment in, 2, 3*f*

basic principles of, 1–2

in Best macular dystrophy, 962–963, 963*f*

for birdshot chorioretinopathy, 1518, 1518*f*

of branch retinal vein occlusion, 1157, 1158*f*

of bullous retinal detachment, 1829–1830

camera in, 2, 3*f*

    aligning, 4, 4*f*–5*f*

in cavernous hemangioma, 2423, 2423*f*

in central retinal artery occlusion, 1139

central serous chorioretinopathy and, 1468–1469, 1472*f*–1473*f*

checklist for, 7*b*

choroidal metastases and, 2622–2623, 2622*f*–2623*f*

choroidal nevi and, 2510

choroidal osteoma and, 2631*f*, 2632

classic choroidal neovascularization, 1349, 1350*f*

Coats disease and, 1191–1193, 1191*f*–1195*f*

cystoid macular edema with vitreoretinal traction, 2201

for diabetic macular edema, 1065–1067

in diabetic retinopathy, 7

for Eales disease, 1667

for epiretinal membrane, 2198, 2198f  
equipment in, 2–4, 2b  
fluorescein solution in, 3–4, 3b  
    injecting, 6, 6.e1f  
fluorescence in, 1–2, 2f  
focusing in, 4–5, 5.e1f  
in fundus anatomy and histology, 7–10, 9f–10f  
hyperfluorescence in, 19–43  
hypofluorescence in, 12–19  
for hypotony maculopathy, 1491, 1491f  
for idiopathic serpiginous choroiditis, 1527, 1527f  
interpretation of, 7–12  
interpreting, of choroidal neovascularization, 1351–1352, 1354f–  
    1356f  
macular telangiectasia and, 1183, 1184f  
in macular translocation, 2242  
matched fluorescein filters in, 3  
of melanocytoma of the optic nerve, 2486, 2487f  
for multiple evanescent white dot syndrome, 1542–1543, 1543f  
for nongeographic atrophy and geographic atrophy, 1320f–1321f,  
    1324, 1325f  
for nonproliferative diabetic retinopathy, 1065–1067, 1066f  
normal, 10–12, 11f  
occult choroidal neovascularization, 1350–1351, 1351f–1353f  
of ocular ischemic syndrome, 1231–1233, 1232t, 1233f–1234f,  
    1233.e1f, 1232.e1f  
overview of, 1349  
“peak” phase of, 12

for persistent placoid maculopathy, 1532–1533, 1533f–1534f  
photographic plan, developing, 6–7, 8f  
photographing in, 4, 4f–5f  
positioning the patient in, 6, 6.e1f  
pseudofluorescence in, 2, 2f  
for punctate inner choroidopathy, 1538, 1538f–1539f  
for relentless placoid chorioretinitis, 1530  
retinal macroaneurysms and, 1152  
in retinal metastases, 2469f  
retinitis pigmentosa and, 879  
in retinoblastoma, 2391, 2391f  
in Stargardt disease, 973–974, 975f  
of sympathetic ophthalmia, 1499, 1500f  
technique in, 4–6  
using stereo photography, 5–6  
UWF imaging and, 147, 148f  
X-linked retinitis pigmentosa, 1002f

Fluorescein leakage, visual acuity and, 1072–1073  
, Fluorescence, 1–2, 2f, 10, 12  
    blocked, 12  
        choroidal, 14–19  
    choroidal, 10, 12  
    preinjection, 22  
    transmitted, 24–41

Fluorinated SO (silicone oil), 1989–1990

Fluorodeoxyglucose PET (F-FDG PET) scanning, sarcoidosis and, 1574

Fluoropyrimidines, proliferative vitreoretinopathy and, [1995–1996](#)

Fluoroquinolones, [1662t](#)

for endogenous endophthalmitis, [1703](#)

treatment infectious endophthalmitis, [2275](#)

Fluoroscopic system, [2584](#)

Focal chorioretinal scars, in hypotony maculopathy, [1493](#)

Focal ERG, [261–263](#)

clinical applications of, [263](#), [265f–266f](#)

principle, method, and characteristics of, [262–263](#), [262f–264f](#)

Focal hyperpigmentation, clinical findings in, [1320](#)

Focal macular ERG (fERG), [270f](#), [271](#)

Focal macular VEP (fVEP), [270f](#), [271](#)

Focal periphlebitis, in patient with intermediate uveitis, [1588f](#)

Focal retinal contraction, retinectomy and, [2061–2063](#), [2063f](#)

Focal/grid laser photocoagulation, for diabetic macular edema, [1081–1082](#), [1082t](#)

Focusing, in fluorescein angiography, [4–5](#), [5.e1f](#)

Folds, choroidal, [316–321](#), [321f](#)

differential diagnosis of, [321t](#)

ocular causes of, [321t](#)

orbital causes of, [321t](#)

Fomivirsen, [1637–1638](#)

Foreign bodies

intraocular, [281](#), [290f–291f](#), [2082t](#)

management of, [2090–2094](#), [2091t](#), [2092f–2095f](#)

subretinal, retinotomy and, [2056–2057](#)

ForeseeHome, [1413](#)

“Forme fruste”, [2446–2447](#)

ForSight VISION4 implantable ocular delivery technology port delivery system (PDS), [836](#)

Foscarnet, [1633–1635](#)

Foscarnet-Ganciclovir Cytomegalovirus Retinitis Trial, [1633](#)

4-2-1 rule, nonproliferative diabetic retinopathy and, [1092b](#)

Fourier domain OCT (FD-OCT), [77–78](#)

Fovea, [9](#), [410](#), [411f](#)

Foveal cyst, macular hole and, [2214](#)

Foveal relocation, principles of, [2241](#), [2241f](#)

Foveal sparing, [129f](#)

Foveomacular retinitis, [1749](#)

Foveoschisis

- myopic, [2147–2148](#)
- surgical procedures for, [2151–2152](#)
  - internal limiting membrane peeling, [2151](#), [2152f](#)
  - macular buckling, [2152](#)
  - tamponade, [2151–2152](#)
  - vitreous separation, [2151](#)
- treatment of, [2150–2152](#)
  - surgical indications of, [2150](#)
  - surgical prognosis of, [2150](#), [2151f](#)

Fovista (PDGF inhibition), for age-related macular degeneration, [1406](#), [1406f–1407f](#)

*FoxN4* gene, [380](#)

Fractalkine, [CX3CL1](#)

Freckles, [2509](#)

Freedman technique, for extraocular muscle surgery, [2244](#), [2245f](#)

Frequency domain OCT, [199](#)

Frequency shifts, in Doppler ultrasound, [275](#)

Fuchs adenoma, [2653](#)

Functional imaging, [200](#)

Fundal exam, intraocular gas injection and, [1966](#)

Fundus

- fluorescein angiography in, [5f](#), [7–10](#), [9f–10f](#)
- image analysis, [206–214](#)
- macular telangiectasia and
  - appearance of, [1181–1182](#), [1181f–1183f](#)
  - autofluorescence, [1182–1183](#), [1184f](#)
- making, [197](#)

Fundus albipunctatus (FA), [257–258](#), [258f](#), [1007f](#), [1012](#)

- molecular basis of, [1012](#)

Fundus appearance, in ARN syndrome, [1709f–1710f](#)

Fundus autofluorescence (FAF), [120](#), [120f–121f](#), [124f–129f](#), [131f](#), [136f–137f](#), [881](#), [882f](#)

- for acute macular neuroretinopathy, [1550](#)
- for acute posterior multifocal placoid pigment epitheliopathy, [1523–1524](#), [1524f](#)
- for acute zonal occult outer retinopathy, [1547](#), [1548f](#)
- of angioid streaks, [1439–1440](#), [1440f](#)
- for birdshot chorioretinopathy, [1519](#)
- central serous chorioretinopathy and, [1468](#), [1470f–1471f](#)
- choroidal nevi and, [2510](#), [2511f](#)
- circumscribed choroidal hemangioma, [2639f](#), [2642](#)
- drusen and, [1314](#), [1314f](#)
- for epiretinal membrane, [2198](#)

high myopia and, [2150](#)  
for idiopathic serpiginous choroiditis, [1528](#), [1528f](#)  
in macular translocation, [2242](#)  
for multiple evanescent white dot syndrome, [1544](#), [1545f](#)  
for nongeographic atrophy and geographic atrophy, [1324](#), [1326f](#)  
for persistent placoid maculopathy, [1533](#)  
for punctate inner choroidopathy, [1539](#), [1540f](#)  
for relentless placoid chorioretinitis, [1531](#)

Fundus camera, [122–123](#)  
development of, [143](#)  
exposure, photochemical retinal injuries from, [1752](#)

Fundus examination, for polypoidal choroidal vasculopathy, [1459](#)

Fundus flavimaculatus, [132f](#)

Fundus perimetry, [180–181](#)

Fundus photograph  
of autosomal dominant radial drusen, [984f–985f](#)  
of Best macular dystrophy, [956f](#), [958f–962f](#)  
of pattern dystrophy, [978f–981f](#)  
of Sorsby fundus dystrophy, [982f–983f](#)  
of Stargardt disease, [967f–973f](#)  
of Stargardt-like dominant macular dystrophy (SLDMD), [977f](#)

Fundus photography, [176](#), [177f](#), [197](#), [2583](#)  
achromatopsia, [1007f](#)  
age-related macular degeneration, bilateral, [2248f](#)  
central areolar choroidal dystrophy, [998f](#)  
choroideremia, [1000f](#)  
advanced stage of, [1000f](#)

X-linked, [1001f](#)  
diffuse choroidal dystrophy, [999f](#)  
drusen characteristics identified with, [1305–1306](#), [1305f–1307f](#)  
gyrate atrophy of choroid and retina, [999f](#)  
Kearns-Sayre syndrome, [1002f](#)  
MTS360, [2247f](#)  
for nonproliferative diabetic retinopathy, [1065](#)  
peripapillary areolar choroidal dystrophy, [998f](#)  
retinitis pigmentosa and, [879](#), [882f](#)  
Stargardt disease, [1003f](#)  
thioridazine retinal toxicity, [1003f](#)  
X-linked retinitis pigmentosa, [1002f](#)

Fundus spectrophotometer, [122](#)

Fundus-controlled microperimetric assessment, [134f–135f](#)

Fundusoscopic lesions, of nonproliferative diabetic retinopathy, [1068–1069](#), [1068f–1069f](#)

Fungal disease, [1644–1645](#)

*FZD4* gene, mutation in, [1263](#)

## **G**

GALILEO Study, clinical trials of, [1803](#)

GALILEO trial, [1173](#)

Gallium scan, sarcoidosis and, [1574](#)

Gamma knife radiosurgery, choroidal metastases and, [2624](#), [2625f](#)

Ganciclovir, [1635](#)  
for ARN syndrome, [1714](#)  
implant, silicone oil (SO) and, [1980](#)

Ganciclovir intraocular device, [1635–1636](#)

insertion of, [1636f](#)

Ganciclovir-Foscarnet, [1634–1635](#)

Ganglion cell death, [383–384](#)

Ganglion cell layer (GCL), [380](#), [409](#)

Ganglion cells, [434–439](#), [1294](#)

- clinical relevance of functional anatomy, [440–441](#), [442f](#)
- color vision and, [439](#)
- for control of pupil diameter and circadian rhythm, [438–439](#)
- dye-injected, in rabbit retina, [436f](#)
- new tools to identify, [439–440](#)
- ON/OFF directional selective, [437f](#)
- visual channel in, [435–438](#)

Gap junctions, [409](#)

Gas, expansile, anti-VEGF and, [2237](#)

Gas resorption, different phases of, [1960](#)

Gas tamponade, in pediatric vitreoretinal surgery, [2176](#)

Gas-gas exchange, [1965](#)

GATE, [German Adaptive Thresholding Estimation \(GATE\)](#)

Gatifloxacin, for endogenous endophthalmitis, [1703](#)

GCL, [Ganglion cell layer; Ganglion cell layer \(GCL\)](#)

GDNF, [Glial cells line-derived neurotrophic factor](#)

, Gemcitabine, retinal toxicity from, [1730–1732](#), [1732f](#)

Gender

- AMD and, [1274](#)
- ocular histoplasmosis and, [1450](#)

Gene delivery, nonviral, [745](#)

Gene expression, [714](#)

Gene expression profiling (GEP), in uveal melanoma, [2535–2538](#), [2536f](#)

Gene structure, [714–715](#), [715f](#)

Gene therapy, [789–791](#)

to cure color blindness, [439](#)

definitions of, [744–745](#)

nonviral gene delivery, [745](#)

nonviral vectors of, [789](#)

ocular applications of, [790–791](#)

preclinical studies, [744–751](#)

retinal, history of, [751–753](#)

for retinal disease, [744–762](#)

of retinitis pigmentosa, [915](#)

subretinal injection of, [749f](#)

surgical delivery and, [749–751](#)

viral vector-mediated gene delivery, [745–749](#), [745t](#), [747t–748t](#)

viral vectors of, [789–790](#)

General anesthesia, ERG recording under, [265](#), [267f](#)

Generation of STR, K Müller cell mechanism for, [242](#), [244f](#)

Genes

delivery of, [783–789](#)

screening for, [719](#)

Genetic factors, diabetic retinopathy studies, [1022](#)

Genetic modification, in retinal degenerations, [590](#)

Genetic testing, [2557](#)

methods, [719–720](#)

Genetic tumor typing, [2610–2611](#)

## Genetics

in Best macular dystrophy, [963](#)

### molecular

retinitis pigmentosa and, [895–902](#)

Usher syndrome, [901–902](#)

in Sorsby fundus dystrophy, [983](#)

in Stargardt disease, [975–976](#)

GENEVA Study Group, on vein occlusion, [1803–1804](#)

Gentamicin, retinal toxicity from, [1729](#), [1729f](#)

GenVec, [834](#)

Geographic atrophy (GA), [87–88](#), [89f–90f](#), [126–129](#), [127f–129f](#), [1285](#)

conclusions for benefit in, [2258–2261](#)

development of, [1320–1321](#), [1320f–1323f](#)

growth of, [1327–1328](#)

HARBOR trial and, [1385–1387](#)

imaging of, [1324–1327](#)

outcome in macular translocation, [2247](#)

outer retina and, [1288](#), [1289f](#)

Geographic helicoid peripapillary choroidopathy (GHPC), [44f](#)

Geography, uveal melanoma and, [2518–2519](#)

German Adaptive Thresholding Estimation (GATE), [870–871](#)

Germinal retinoblastoma, [2375–2376](#), [2382](#)

Germline cells, [713](#)

## Gestational diabetes

diabetic retinopathy and, [1777](#)

insulin therapy for, [1060](#)

GFP, [Green fluorescent protein \(GFP\)](#)

Giant cell arteritis, [1614–1615](#)

The American College of Rheumatology 1990 Criteria for the Classification of, [1614b](#)

articular and systemic disease of, [1614](#)

epidemiology of, [1614](#)

ocular disease of, [1614–1615](#)

ocular ischemic syndrome and, [1235](#)

treatment of, [1615](#)

Giant choroidal nevus, [2505](#)

Giant retinal tear, [1763–1764](#), [1763f](#), [2072–2080](#)

alternative techniques, [2077–2078](#)

anterior retinal flap, management of, [2076](#)

contraction and fibrosis of, retinectomy for, [2065](#), [2067f](#)

conversion to 360-degree tear, [2076](#)

cryopexy, [2074](#)

definition of, [2072](#)

etiology of, [2072–2073](#)

fellow eye, management of, [2078–2079](#)

fundus photograph, [2073–2074](#), [2074f](#)

iatrogenic, [2072–2073](#)

internal tamponade, [2077](#)

intraocular lens, management of, [2075](#)

laser photocoagulation, [2074](#)

lens management, [2075](#)

management of, history of, [2073](#)

nonsurgical treatment, role of, [2074](#)

outpatient fluid-gas exchange, [2074](#)

- pathogenesis of, [2073](#)
- perfluorocarbon liquid (PFCL), [2076–2077](#)
  - additional steps in, [2078](#)
  - air exchange, [2077](#)
  - injection of, [2076](#)
  - silicone oil exchange, [2077](#), [2077f–2078f](#)
- perfluorocarbon liquid (PFCL) and, [1970–1972](#), [1971f–1972f](#)
- preoperative evaluation, planning and, [2073–2074](#), [2074f](#)
- proliferative vitreoretinopathy, [1856](#), [2074](#)
  - eyes with, [2076](#)
- results, [2078](#)
- retina, mobilizing, [2076](#)
- retinopexy, [2076–2077](#)
- scleral buckling surgery
  - role of, [2074–2075](#)
  - technique of, [2075](#)
- silicone oil and, [1979](#)
- ultrasonographic diagnosis of, [2074](#), [2074f](#)
- visualization, [2075](#)
- vitrectomy, [2075–2076](#)
- vitreoretinal surgery, [2075](#)
- vitreous base, radical excision of, [2076](#)
- vitreous surgery, [2075–2078](#)

Gilenya, [Fingolimod](#)

Glaucoma, [611](#), [786](#), [870](#), [2451](#)

- depletion of ganglion cells in, [441f](#)
- diabetic retinopathy and, [1044–1045](#), [1045f](#)

- neuroprotection and, [811](#)
- neurotrophic factors in, [812–813](#)
- optic disc drusen with, [1790](#)
- pneumatic retinopexy for, [1945](#)
- retinectomy for, [2057](#)
- in ROP, [1256](#)
- scleral buckling surgery and, [1911](#), [1913f](#)
- snowflake vitreoretinal degeneration and, [939](#)
- surgery, [2114–2115](#)

Glaucoma filtration surgery, postoperative infection endophthalmitis, [2272](#)

Glaucomatous optic neuropathy, [811–812](#)

Glial cells

- proliferation, [575f](#)
- proliferative vitreoretinopathy and, [1857–1858](#)
- spatial buffering by, [226](#), [227f](#)

Glial cells line-derived neurotrophic factor (GDNF), [833](#)

Glial fibrillary acidic protein (GFAP), [670](#), [1868](#)

- during retinal detachment, [695–696](#), [696f](#)

Glinides, for diabetes mellitus, [1041–1042](#)

Glioma, [2653](#)

Globe

- shape of, changes in, [276–277](#)
  - microphthalmos, [276](#), [279f](#)
  - phthisis, [276–277](#), [279f](#)
  - staphyloma, [276](#), [278f](#)
- volume, replace of, intraocular gas and, [1960](#)

$\beta$ -globin gene, [1203](#)

“Globular vitreous opacities”, [2462–2468](#)

Glucosate solvent, [48](#)

Glucose, RPE and, [459](#)

Glucose transporter (GLUT1), [818](#)

Glucose transporters, diabetic retinopathy and, [1042–1043](#)

GLUT1, [459](#)

GLUT3, [459](#)

Glutamate

- analogs, [239](#)
- hyperpolarizing response to, [423–424](#)
- photoreceptors release in dark, [417](#)

Glutamate-glutamine cycle, [475–480](#), [475f](#)

Glutathione peroxidase 1 (Gpx1), [817–818](#)

Glycemia, diabetic retinopathy and, [1023–1026](#)

Glycosaminoglycans (GAGs), [527–528](#)

Glycosides, cardiac, uveitis from, [1739](#)

GM-CSF, [Granulocyte-macrophage colony-stimulating factor](#)

GNA11 gene, mutations in, [2533–2534](#), [2534f](#)

GNAQ gene, mutations in, [2451](#), [2533–2534](#), [2534f](#)

Gold nanoparticles, [791](#)

Gold Standard, [205](#)

Goldberg stages, of proliferative sickle retinopathy, [1210–1211](#)

Goldmann and Humphrey 30-2 visual field perimetry, [363f](#)

Goldmann kinetic perimeter

- for autosomal dominant retinitis pigmentosa, [871f](#)
- for simplex RP, [871](#), [872f–873f](#)

Goldmann tonometer, [791](#)

Goldmann visual field (GVF), [350](#), [351f](#)  
testing, [159](#)

Goldmann-Favre vitreotapetoretinal degeneration, [937t](#)  
differential diagnosis of, [941](#)  
general features of, [946](#)  
ocular features of, [946](#), [946f](#)

Goldmann-Witmer coefficient (GWC), for ARN syndrome, [1714](#)

*Gorgonia flabellum*, [1209](#), [1210f](#)

G-protein-coupled-receptor (GPCR), [793–794](#)

Graft failure, in RPE, [2318–2319](#), [2319f](#)

Graft implantation, sites and preparations of, in photoreceptor transplantation, [2321–2322](#)

Granular cell tumor, [2655](#)  
, Granulocyte-macrophage colony-stimulating factor (GM-CSF), [460t](#)

Granulocytopenia, [1632](#)

Granuloma, peripheral, [1686–1687](#), [1688f](#)

Granulomatosis with polyangiitis, [1616–1617](#)  
articular and systemic disease of, [1616](#)  
epidemiology of, [1616](#)  
ocular disease of, [1616–1617](#)  
treatment of, [1617](#)

Granulomatous inflammatory mass, sarcoidosis and, [1579f](#)

Gravity, [1958](#)

Green cones, [413](#), [413f](#)

Green fluorescent protein (GFP), [752f](#)

Grid macular laser, for macular edema, [1161](#), [1161f](#)

*GRM6* gene, mutations in, [260](#)  
Group I Coats disease, [1188](#)  
Group II Coats disease, [1188](#)  
Group III Coats disease, [1188](#)  
Groupe d'Evaluation Français Avastin *vs.* Lucentis (GEFAL) study, [1395–1397](#)  
Grouped CHRPE, [2490–2491](#), [2491f](#)  
Grouped pigmentation of retina, pseudoretinitis pigmentosa differential diagnosis, [895](#), [896f](#)  
Growth factors, [1858](#)  
    in epiretinal membrane, [2196](#), [2197t](#)  
Growth-associated protein (GAP)-43, [693](#)  
Guanylyl cyclase, dependence of, [394](#)  
*Gucy2d* gene, [376t](#)  
Gyrate atrophy of the retina, [353](#), [356f](#)  
    and choroid, [999–1000](#), [999f](#)

## H

Haag-Streit system, [168](#), [169f](#)  
HAART Era, HIV disease/CMV retinitis in, [1640–1641](#)  
*Haemophilus influenzae*, infectious endophthalmitis, [2268](#)  
Half-height full-width (HHFW) algorithm, [209](#)  
Half-value (HVL), [2567](#)  
Haller's layer, [48](#), [50f–51f](#)  
Halo nevus, [2503–2505](#)  
Halorhodopsin (HaloR), [794](#)  
Hamartia, [2446–2447](#)  
Hamartoma, [2446–2447](#), [2643](#)

“Hand held laser systems,” photothermal retinal injuries in, [1748](#), [1748f](#)

## Haplogroups

associations of, within retinal disease, [725–726](#)

definition of, [725](#)

genetics, in ocular toxoplasmosis, [1681–1682](#)

HARBOR study, [1385–1387](#), [1387f](#)

## Hard exudates

distribution of, diabetic macular edema and, [1066f](#), [1070–1071](#)

on ophthalmoscopy, [1068](#), [1069f](#)

HbSC disease, [1203–1204](#)

Head, positioning of, for scleral buckling surgery, [1891](#), [1891.e1f](#)

Head posture, after intraocular gas injection, [1965–1966](#)

Head-down positioning, [66](#)

Heat shock proteins, [823–824](#), [824f–825f](#)

Heavier-than-water perfluorocarbon fluid, [2035–2036](#)

Heavy tamponade, [1989–1994](#)

anti-vascular endothelial growth factor (VEGF) and, [1997–1998](#)

complications in, [1992–1994](#)

adherent silicone oil, [1994](#)

cataract formation, [1993](#)

corneal toxicity, [1992–1993](#)

emulsification, [1993](#)

hypotony, [1994](#)

intraocular inflammation, [1993](#)

raised intraocular pressure, [1994](#)

redetachment and proliferative vitreoretinopathy, [1994](#)

sticky silicone oil, [1993–1994](#)  
newer generation of, [1990–1991](#), [1990t](#), [1991f](#)  
technique, [1991–1992](#), [1992f](#)

Heavy tamponade Study (HSO Study), [1991](#)

Heidelberg Retina Flowmeter (HRF), [185](#)

Heidelberg Spectralis non-contact ultrawide-field module, [145](#)

HELLP syndrome, [Hemolysis, elevated liver enzymes, and low platelets \(HELLP\) syndrome](#)

Helmholtz ophthalmoscope, [177f](#)

Helminthic disease, [1685–1699](#)  
cysticercosis, [1696–1697](#)  
diffuse unilateral subacute neuroretinitis, [1690–1695](#)  
history of, [1685](#)  
ocular toxocariasis, [1685–1690](#)  
onchocerciasis, [1695–1696](#)

Helminths, infectious endophthalmitis, [2270](#)

Helper-independent (“guttled”) adenovirus, [745t](#)

Hemangioma, choroidal, [316](#), [317f](#)  
nonrhegmatogenous retinal detachment in, [1839–1840](#), [1839f](#),  
[1839.e1f](#)

Hemangiopericytoma, [2657](#)

Hematogenous dissemination, retinal metastases and, [2461](#)

Hematologic alterations, CRVO and, [1169b](#)

Hematoporphyrin derivatives (HpD), [2605](#)

Hemicholinium-3, retinal adhesion and, [511](#)

Hemodialysis exudative detachment, [1846–1847](#)

Hemoglobin C (Hb C), [1203](#)

Hemoglobin S (Hb S), [1203](#)

Hemoglobinopathies, [1203–1218](#)

Hemolysis, elevated liver enzymes, and low platelets (HELLP) syndrome, [1241](#), [1771](#)

amniotic fluid embolism in, [1774](#), [1775f](#)

central serous chorioretinopathy in, [1773](#)

choroidopathy in, [1772–1773](#)

cortical blindness in, [1773](#)

cortical vision loss in, [1773](#)

disseminated intravascular coagulopathy in, [1774](#)

intracranial hemorrhages in, [1773](#)

occlusive vascular disorders in, [1773](#)

retinal artery occlusion in, [1773–1774](#)

retinal vein occlusion in, [1774](#)

Susac syndrome in, [1774](#)

thrombotic thrombocytopenic purpura in, [1774](#)

uveal melanoma in, [1774–1776](#)

Hemorrhage, [1241–1243](#)

causing hypofluorescent blockage, [14](#)

    intraretinal, [16f](#)

    preretinal, [15f](#)

    subretinal, [17f](#)

choroidal, due to drainage retinotomy, [2056](#)

due to relaxing retinectomy, [2068](#)

intracranial, [1773](#)

in NPDR, [1066f](#), [1068](#), [1068f](#)

in optic disc drusen, [1790](#)

persistent vitreous, [1668–1670](#)

retinal macroaneurysms and, [1151](#), [1152f](#)  
submacular, [2234–2237](#)  
subretinal, [2234](#), [2509](#)  
    retinotomy and, [2056](#)  
vitreous, [280](#), [283f–285f](#)  
    etiology of, [322t](#)  
    pathogenesis, [322f](#)  
    pediatric vitreoretinal surgery for, [2178](#)  
    persistent, [1668–1670](#)

Hemorrhagic events, DIC and, [1240b](#)

Hemorrhagic retinal detachment, [1825](#)

Hemorrhagic retinal pigmented epithelium detachment, [91](#), [92f](#)

Heparin, proliferative vitreoretinopathy and, [1997](#)

Hepatocyte growth factor (HGF), [460t](#)  
    in patients with PVR, [1869](#)  
    proliferative vitreoretinopathy and, [1859](#)

Hepatocyte sinusoidal (basolateral) membrane, [47](#)

Hereditary choroidal diseases, [997–1005](#)  
    brief classification of, [997b](#)  
    clinical phenotypes resembling, [1001–1003](#)

Hereditary vitreoretinopathies, pediatric vitreoretinal surgery for, [2182–2190](#)

Heredopathia atactica polyneuritiformi, [891](#)

Heritable retinoblastoma, [2382](#)

Herpes simplex virus (HSV)  
    in ARN syndrome, [1712](#), [1712f](#)  
    ocular syphilis *vs.*, [1674t](#)

- pars planitis, [1591](#)
- presentation and clinical findings of, [1586–1587](#), [1587f](#), [1589f](#)
- in rheumatic disease, [1598](#)
- sarcoidosis, [1591](#)
- treatment of, [1591–1594](#)

unilateral disease, [1591–1593](#), [1592f](#)

Internal limiting membrane (ILM), [362](#), [673](#)

- effect of, [681–682](#)
- peeling, [2369–2370](#)
  - adverse anatomical effects of, [2225](#), [2226f](#)
  - in epiretinal membrane, [2199–2200](#)
  - in macular hole, [172](#), [172f](#)
  - for tractional macular edema, [2203](#), [2204f](#)
  - in uveitic macular edema, [2205](#)

Internal tamponade, intraocular gas and, [1957](#), [1959](#), [1959t](#)

International Classification System, in intraocular retinoblastoma, [2385](#), [2385b](#), [2386f](#)

International League of Associations of Rheumatologists (ILAR) classification, of juvenile idiopathic arthritis, [1604b](#)

International Society for the Clinical Electrophysiology of Vision (ISCEV), [228](#), [228b](#), [229f](#)

International Vitreomacular Traction Study, group classification of, [2216](#), [2217t](#)

International Workshop on Ocular Sarcoidosis (IWOS), [1579](#)

Interphotoreceptor matrix (IPM), [704](#)

- properties, of retinal adhesion, [509–510](#), [509f–511f](#)
- RPE cells and, [455](#)

Interphotoreceptor retinoid-binding protein (IRBP), [661](#)

- mutations, [601](#)

Interpretation, in retinal image analysis, [203](#)

Intertrabecular marrow spaces, choroidal osteoma and, [2632](#)

Intervening extracellular matrix, of vitreous, [551](#)

Intraarterial chemotherapy (IAC), for retinoblastoma, [2394–2395](#), [2395f–2396f](#)

Intracameral vancomycin, retinal toxicity from, [1730](#)

Intracellular edema, [668](#)

Intracellular neurotrophic pathways, modulation of, [821t](#), [823–826](#)

Intracellular trafficking, abnormal, [906](#)

Intracranial hemorrhage, [1773](#)

Intraocular biopsy

- complications of, [2306](#)
- indications for, [2297t](#)
- metastatic uveal melanoma and, [2609](#)

Intraocular ciliary neurotrophic factor (CNTF), [815f](#)

Intraocular cysticercosis, [1697](#)

Intraocular foreign body (IOFB), [2082t](#)

- management of, [2090–2094](#), [2091t](#), [2092f–2095f](#)
- in ocular trauma, [1870](#)
- PFCL and, [1972](#)

Intraocular gas, [1957](#)

- clinical applications of, [1961–1965](#)
- complications in, [1966–1967](#)
  - anterior chamber, gas in, corneal decompensation and, [1967](#)
  - cataract formation, [1966](#)
  - hypotony, [1967](#)
  - intraocular lens capture, [1967](#)
  - raised intraocular pressure, [1966](#)
  - subretinal gas, [1967](#)
- in displacement of subretinal blood, [1965](#)
- dynamics of, [1960–1961](#)
  - altitude, changes in, [1960–1961](#)

- under general anesthesia, [1960](#)
- resorption of, different phases of, [1960](#)
- functions of, [1959–1960](#)
  - globe volume, replace of, [1960](#)
  - internal tamponade and, [1959](#), [1959t](#)
  - postoperative visualization, [1959–1960](#)
  - unfolding and folding, of retina, [1959](#)
- in macular hole surgery, [1965](#)
- management of, [1966–1967](#)
- physical properties of, [1957–1959](#), [1957b](#), [1957t–1958t](#)
- in pneumatic retinopexy, [1943–1944](#), [1962–1964](#), [1964f](#)
- postoperative care in, [1965–1966](#)
  - altitude, changes in, [1966](#)
  - fundal exam in, [1966](#)
  - head posture, after injection of, [1965–1966](#)
  - intraocular pressure measurements, [1966](#)
  - laser photocoagulation, [1966](#)
- in postvitrectomy gas exchange, [1965](#), [1965f](#)
- preparation for injection of, [1961](#), [1961f–1962f](#)
- in scleral buckling, [1964–1965](#)
- surgical techniques of, [1961–1965](#)
- in vitrectomy, [1962](#), [1963f](#)

Intraocular hemorrhage, proliferative diabetic retinopathy and, [2122–2123](#)

, Intraocular infections, [280](#), [287f–289f](#)

Intraocular inflammation

- choroidal osteoma and, [2632](#)

- heavy tamponade and, [1993](#)
- Intraocular injection, postoperative infection endophthalmitis, [2272–2273](#)
- Intraocular lens capture, [1967](#)

Langerhans cell histiocytosis, [2657](#)

Laplace's Law, [1983](#)

Large tumors, [2570](#)

Large vessel vasculitides, [1614–1615](#)

Large-scale multielectrode array, [439](#)

Laser classes, [1752](#)

Laser demarcation

for retinal dialysis, [2010](#)  
for round hole retinal detachment, [2008–2009](#), [2009f](#)  
for “U” (horseshoe) tears, [2010–2011](#)

Laser Doppler flowmetry (LDF), [185](#)

Laser Doppler velocimetry (LDV), [184–185](#)

Laser injuries, real, diagnosis of, [1747](#)

Laser interferometry, [198](#)

Laser monochromatic light, [47](#)

Laser photocoagulation, [66](#), [2556](#), [2576](#)  
for angioid streaks, [1441](#)  
circumscribed choroidal hemangioma, [2644](#)  
for Coats disease, [1196–1197](#), [1198f](#)  
in CRVO, [1174](#)  
for extrapapillary retinal hemangioblastomas, [2432–2433](#)  
focal/grid, for diabetic macular edema, [1081–1082](#), [1082t](#)  
intraocular gas injection and, [1966](#)  
mechanism of, [675](#)  
for ocular histoplasmosis, [1452](#)  
pattern scanning, [853–854](#)  
for retinal detachment, [2026–2027](#)  
on slit lamp system, [847f](#)

Laser pointers, photothermal retinal injuries in, [1748](#), [1748f](#)

Laser therapy  
aberrations, [846–847](#)  
age-related macular degeneration, [854](#)  
basics of lasers, [845–848](#), [846f](#)  
contact lenses use, [847–848](#), [847t](#)

- diabetic retinopathy, 854, 854f
- extrafoveal neovascular lesions, 854
- laser beam delivery to tissue, 846–848
- light, interactions with tissue, 848–857
- necrosis, 849–850, 850f
- optical properties of eye, 844–845
- pattern scanning laser photocoagulation, 853–854
- photocoagulation, 851–853, 852f–853f
- photodisruption, 855–857
- retinal lesions, healing of, 852f, 853
- selective RPE therapy (SRT), 856–857, 857f
- temperature monitoring in retina, 857
- tissue change monitoring in real time, 857
- wavelengths selection of, 854–855

#### Laser treatment

- in branch retinal vein occlusion
  - of macular edema, 1161–1162, 1161f
  - of neovascularization, 1160–1161, 1160f
- clinical trials on, 1804–1806
- for macular edema, 674–675, 675f–676f
- of peripheral retinal ischemia, 675
- for retinoblastoma, 2397–2398, 2397f–2398f
- of well-defined choroidal neovascular lesions, 1365

Laser trials, early, for proliferative diabetic retinopathy, 1105

Laser *versus* cryotherapy, for retinal detachment, 2013

#### Lasers

- basics of, 845–848, 846f

delivery to tissue, [846–848](#)  
optical fibers, [846](#), [847f](#)  
PVR and, [2036](#)  
in ROP, [1259](#)  
treatment for, circumscribed choroidal hemangioma, [2644](#)

Latanoprost, topical, cystoid macular edema from, [1732](#), [1734f](#)

Late extravascular hyperfluorescent leakage, in normal eye, [31](#)

Late infantile-onset form, retinitis pigmentosa and, [891](#)

Latent tuberculosis, [1660](#)

Late-onset retinal degeneration (LORD), [535–536](#)

Late-phase leakage of an undetermined source (LLUS), [53–54](#)

Lattice wicker, [561f](#)

Laurence-Moon-Bardet-Biedl syndrome, [890](#)

Layer-by-layer perimetry, [367](#)

LCA, [Leber congenital amaurosis \(LCA\)](#)

Lea numbers low-contrast acuity test, [344f–345f](#)

Leakage, in transmitted fluorescence, [31–32](#)  
choroidal, [34–41](#), [38f–43f](#)  
disc, [34](#), [34f](#)  
retinal, [34](#), [35f–37f](#)  
vitreous, [32–34](#)

Leber congenital amaurosis (LCA), [834](#)  
gene augmentation therapy for, [754](#), [757f](#)  
retinitis pigmentosa differential diagnosis, [889–890](#)

Leber hereditary optic neuropathy (LHON), [727t](#)  
gene augmentation therapy for, [755](#)  
mutations, [726](#)

Lecithin-retinol acyltransferase gene (*LRAT*) mutations, 601

LED contact lens electrode, 265

Leiomyoma, 2655–2656, 2656f

Lens, management of, in pediatric vitreoretinal surgery, 2173–2174

Lens epithelial-derived growth factor (LEDGF), 823–824

Lens extraction

- biochemical changes after, 569
- inflammatory changes after, 569
- posterior vitreous detachment following, 569
- structural changes after, 569, 569f
- vitreoretinal changes after, 569

Lens subluxation and dislocation, 2083–2084, 2083f–2084f

Lens/corneal changes, regressed ROP and, 1256

Lensectomy, for stage 5 ROP, 2163, 2163f–2165f

Lens-sparing vitrectomy, for stage 4A ROP, 2162, 2162f–2163f

Lentiviral vectors, 834

Lentiviruses, 745t, 834

Leopard-spot retinal pigmentations, in uveal effusion syndrome, 1486, 1486f

Leptospiral uveitis, treatment for, 1678

Leptospirosis, differential diagnosis of, 1678t

Less-than-total carotid artery obstruction, in ocular ischemic syndrome, 1236–1237

let7, 380

Leukemia, 2661–2667

- anemia, manifestations of, 2664–2665
- clinical manifestations of, 2661–2662
- hyperviscosity, manifestations of, 2665–2666, 2665f

- incidence of, [2661](#)
- infiltrates, [2662–2664](#), [2662f](#)
- opportunistic infections in, [2666](#), [2666f](#)
- prevalence of, [2661](#), [2661t](#)
- prognosis in, [2666](#)
- retinal detachment and, [1842](#), [1843f](#)
- systemic classification of, [2660–2661](#)
- thrombocytopenia, manifestations of, [2664–2665](#)
- treatment of, [2666–2667](#)

Leukemia inhibitory factor receptor- $\beta$  (LIFR- $\beta$ ), [813](#)

Leukemic hypopyon, [2660](#), [2660f](#)

Leukemic retinopathy, [2664](#), [2664f](#)

Leukocoria, [316–321](#), [322f](#)

- differential diagnosis of, [322t](#)
- in retinoblastoma, [2382](#), [2382f](#), [2388](#)

Leukocyte extravasation, [668–669](#)

Leukostasis, [630](#), [670](#)

Levofloxacin, [1662t](#)

LHON, [Leber hereditary optic neuropathy \(LHON\)](#)

Lidocaine, [1891](#)

Ligand binding, to vascular endothelial growth factor, [493](#)

Light

- adaptation, [326](#)
- damage, to retina, [614–615](#)
- exposure, age-related macular degeneration and, [1376](#)
- photochemical interactions, [848–849](#)
- in ROP, [1258](#)

tissue interactions with, [848–857](#)

Light increment sensitivity (LIS), [134f](#)

Light peak, [225f](#), [231](#)

Light Reduction in Retinopathy of Prematurity (LIGHT-ROP), multicenter study of, [1815](#)

Light-activated glutamate receptor (LiGluR), [794](#)

Light-emitting diodes (LEDs), ERG recordings by, [263–269](#), [267f](#)  
during eye surgery, [265](#), [268f](#)  
under general anesthesia, [265](#), [267f](#)  
short-wavelength cone ERG and, [265–269](#), [268f](#)

Light-induced photoreceptor degenerations, [817–819](#)

Light-sensitive azobenzene linker, [794](#)

Limited extrascleral extension, in enucleation, [2563](#)

Lincoff's rules, [1891](#), [1892f](#)

Linear accelerator-based radiosurgery, choroidal metastases and, [2624–2625](#)

Linkage, [715–716](#), [719–720](#)

*LIPC* gene, [1278](#)

Lipid exudation, [89](#)

Lipid lowering, in diabetic retinopathy, [1028](#)  
, Lipid trafficking, through Bruch's membrane, [1286](#)

Lipofuscin, [120–121](#)  
in age-related macular degeneration, [1375](#)  
pigment, accumulation of, [2638](#)  
in RPE, [1287](#)

Lipofuscinosis, ceroid, neuronal, [891–893](#), [892f–893f](#)

Lipoprotein HDL3, [47](#)

Lipoproteins, Bruch's membrane, [524–527](#), [525f–526f](#)

natural history of, [526](#)

Liposomes, [783](#), [831](#), [835](#)

Liquid perfluorocarbon, [1928–1929](#), [1929f](#)

Liraglutide, for diabetes mellitus, [1058](#)

Lisch nodules, [2447](#)

*Listeria monocytogenes*, infectious endophthalmitis, [2268](#)

Liver

- biopsy, [1574t](#)
- metastatic uveal melanoma and, [2608](#)

Liver function tests (LFTs), metastatic uveal melanoma and, [2608](#)

Liver metastases, treatment of, [2610](#)

Local ERG, [226–227](#)

Local resection, [2557](#)

Local tumor

- control, [2596](#), [2596f](#)
- response, [2573–2574](#)

Loculated fluid, [1354](#)

Long-acting intraocular gas, [1976](#)

Long-chain polyunsaturated fatty acids (LCPUFAs), [825–826](#)

Longer wavelength OCT imaging, [200](#)

“Long-term nonprogressors”, [1626](#)

Los Angeles Latino Eye Study (LALES), [1021](#)

Lossy image compression, [201](#)

Low luminance visual acuity/SKILL card, [1414](#)

Low penetrance retinoblastoma, [2378–2379](#)

Low-intensity light exposure, of retina, [614–615](#)

Low-molecular-weight heparin (LMWH), proliferative

vitreoretinopathy and, [1997](#)

Low-tension glaucoma, [811–812](#)

*L<sub>p</sub>*

    of Bruch's membrane, determining, [529](#), [529f](#)

    in other species, [530](#)

Lucentis, [679](#)

Lucentis Compared to Avastin Study (LUCAS), [1397](#)

Luminance-based testing, [1413–1414](#)

Lung biopsy, transbronchial, [1574t](#)

Lutein, [582–583](#), [819–820](#), [1408](#)

    supplements, [913](#)

Lyme disease

    treatment of, [1677t](#)

    uveitis associated with, [1675–1677](#)

        diagnosis of, [1676–1677](#)

        diagnostic criteria and case classification of, [1676t](#)

        differential diagnosis of, [1677](#)

        disease course and outcome of, [1677](#)

        epidemiology of, [1675–1676](#)

        ocular manifestations of, [1676](#), [1676f](#)

        pathogenesis of, [1675–1676](#)

        treatment of, [1677](#)

Lymphocyte, activation of, in adaptive immunity, [657–658](#)

Lymphoma, [2656–2657](#), [2656f–2657f](#), [2667–2671](#)

    Burkitt, [2670](#), [2671f](#)

    cells, trafficking of, [2675](#)

    Hodgkin, [2668](#), [2670f](#)

multiple myeloma and, [2671](#)  
mycosis fungoides and, [2669–2670](#)  
non-Hodgkin, [2667–2668](#), [2667f–2669f](#)  
retinal detachment and, [1841–1842](#), [1842f](#)  
systemic classification of, [2660–2661](#)  
treatment of, [2668–2669](#)  
Waldenström macroglobulinemia and, [2671](#)

Lysosomal degradation, in RPE, [1287](#)

## M

M notation, [342](#)

Macular telangiectasia type 2 (MacTel2), [105](#), [107f](#)

## Macular traction

evidence-based trials and, [2125–2126](#)

proliferative diabetic retinopathy and, [2109](#)

## Macular translocation

360-degree, [2240–2253](#), [2243f](#)

advantages of, [2251](#)

animal studies, [2240](#)

background and rationale, [2240–2241](#)

complications, [2248–2250](#), [2249t](#)

evolution of technique, [2240–2241](#)

exclusion criteria for, [2242b](#)

fundus photograph, [2247f](#)

historical perspective, [2240–2241](#)

inclusion criteria for, [2242b](#)

neovascular disease, age-related macular degeneration  
outcomes, [2245–2247](#)

non-AMD diagnoses, [2248](#)

non-neovascular disease, age-related macular degeneration  
outcomes, [2247](#)

postoperative management of, [2244](#)

preoperative considerations, [2241–2242](#)

principle of foveal relocation, [2241](#), [2241f](#)

retinal changes after, [2250](#)

retinal detachment repair, as complication in, [2250](#)

RPE changes after, [2250](#)

surgical technique for, [2242–2243](#)

age-related macular degeneration (AMD), [2255](#)

for ocular histoplasmosis, [1454](#)

surgery, retinotomy and, [2056](#)

## Maculopathy

myopic traction, [1431](#), [1434f](#)

solar, [1749–1750](#), [1749f–1750f](#)

Welder's, [1749–1750](#), [1749f–1750f](#)

## *Maf* gene, [376t](#)

## Magnetic resonance imaging (MRI), [189–190](#)

choroidal osteoma and, [2634](#), [2634f](#)

circumscribed choroidal hemangioma, [2642](#)

Coats disease and, [1193](#)

liver metastasis and, [2608–2609](#)

retinal and choroidal, [190](#), [190f](#)

in retinoblastoma, [2390](#)

sarcoidosis and, [1574](#)

## Magnocellular nevus, [2484](#), [2505](#), [Melanocytoma](#)

## MAHALO study, [1339–1340](#)

## Maillard reaction, [1041](#)

## Malattia Leventinese, [984–985](#)

## Malattia Leventinese-Doyne honeycomb retinal dystrophy (ML-DH), [535–536](#)

## Malignancy, nonocular, history of, [2518](#)

## Malignant melanoma, abnormal choroidal vascular fluorescence due to, [33f](#)

## Mammalian retina

DNA methylation in, [734–735](#)

function and anatomy of, [408–450](#)

gross retinal morphology, [410–412](#)

neuronal communication: chemical and electrical, [409–410](#)

visual illusions and multiple channels, [408–409](#)  
miRNA in, [735](#)  
Mannitol, retinal adhesion and, [507](#), [507f–508f](#), [514–515](#)  
MAR, [Melanoma-associated retinopathy \(MAR\)](#); [Melanoma-associated retinopathy \(MAR\) syndrome](#)  
Marcus Gunn pupil, [2484](#)  
Marfan syndrome, pediatric vitreoretinal surgery for, [2185](#)  
MARINA Study Group  
for ranibizumab, [1382](#), [1385f](#)  
on treatment of neovascular age-related macular degeneration, [1809](#)  
Marshall syndrome  
differential diagnosis of, [942–943](#)  
extraocular features of, [942](#)  
general features of, [941](#)  
Masked fluorescence, [Blocked fluorescence](#)  
Masquerade syndrome, leukemia and, [2663–2664](#)  
Massachusetts Eye and Ear Infirmary (MEEI), [2586](#)  
Massive perivenous infiltrates, in lymphoma, [2667](#), [2667f](#)  
Massive subretinal hemorrhage, neovascular AMD and, [1346–1347](#)  
Maternally inherited diabetes and deafness (MIDD), [727t](#), [989](#), [989f](#)  
*Math3* gene, [380](#)  
Matrix metalloproteinase inhibitor, for age-related macular degeneration, [1413](#)  
Matrix metalloproteinases (MMPs), [455–456](#), [641](#), [672](#), [1378–1379](#)  
as angiogenic factor in neovascularization, [647](#)  
Matrix pattern, [2541f](#)  
Matrix-based formulations, [833](#)

Matrix-based systems, [832f](#)

Nerve fiber edema, in blocked retinal fluorescence, [14](#)

Nerve growth factor (NGF), [460t](#), [812](#)

topical delivery of, [836](#)

Neural cell adhesion molecule (N-CAM), [452](#)

Neural induction, [375–376](#)

Neural plate, [375–376](#)

Neural progenitor cells (NPCs), [2312](#)

Neural retina, [378](#)

- detachment and reattachment, cellular effects of, [689–702](#)

Neurocysticercosis, [1696](#)

*NeuroD1* gene, [380](#)

Neurofibroma, [2655](#)

Neurofibromatosis, [2447–2450](#), [2508](#)

Neuroimaging, circumscribed choroidal hemangioma, [2642](#)

Neurologic manifestations, of TSC, [2438–2439](#)

Neuromodulators, [821–822](#), [821t](#)

Neuronal cell classes, six major, [412](#)

Neuronal ceroid lipofuscinosis, [891–893](#), [892f–893f](#), [955f](#)

Neuronal communication, [409–410](#)

Neuronal degeneration, [673](#)

Neurons, retinal

- classification of, [412](#)
- techniques to label and visualize, [410–412](#)

Neuropathy, ataxia and retinitis pigmentosa (NARP)/Leigh syndrome, [727t](#)

Neuroprotectin 1 (NPD1), [460t](#)

Neuroprotection, [811–830](#)

- for age-related macular degeneration, [1411–1413](#)
- for cell death, [615–616](#), [615t](#)

CNTF phase I for human photoreceptor degeneration, [814–816](#)  
CNTF protein and historical selection of, [813–814](#)  
goal of, [811](#)  
history and definitions of, [811–813](#)  
neurotrophins, delivery of, [816–826](#)  
photoreceptor degenerations, technology for endpoints for, [816](#)  
retinitis pigmentosa and, [813](#), [916–917](#)  
with small molecules, [820–826](#), [821t](#)  
through serotonin pathway, [813](#)

Neurosyphilis, [1645](#)

Neurotech ECT (encapsulated cell technology) devices, [813–814](#),  
[814f–815f](#), [816](#)

Neurotech NT-501 CNTF devices, [816](#)

Neurotransmitters, [821–822](#)

Neurotrophic factor, [816](#)  
ciliary, [768](#)  
therapy, [786](#)

Neurotrophin 3 (NT3), [384](#), [460t](#)

Neurotrophins, neuroprotection and, [816–826](#)

Nevus  
definition of, [2502](#)  
giant choroidal, [2505](#)  
halo, [2503–2505](#)  
, magnocellular, [2505](#)  
management of, [2511](#)  
types of, [2503–2505](#)

Nevus of Ota, [2506f](#)

New vessels, in proliferative diabetic retinopathy  
development and proliferation of, [1095–1098](#), [1095f–1097f](#)  
direct (local) treatment of, [1112](#)  
preretinal, origin and early recognition of, [1092–1094](#), [1092f–1093f](#)

Next-generation sequencing (NGS), [720](#)

*NF1* gene, mutation in, [2447](#)

NGF, [Nerve growth factor](#)

Nicotinamide adenine dinucleotide phosphate (NADPH) oxidase, [817](#)

Nicotinic acid, cystoid macular edema from, [1732](#), [1733f](#)

Night blindness, [Congenital stationary night blindness \(CSNB\)](#)

Night vision, [325–339](#)

NIH, [National Institutes for Health \(NIH\)](#)

Nitric oxide (NO), SCD and, [1204](#)

Nitric oxide synthase (NOS) inhibitors, [817](#)

Nitrofurantoin (Macrochantin), crystalline retinopathy from, [1738](#)

Nitrous oxide (N<sub>2</sub>O), intraocular gas and, [1960](#)

NLRP receptor molecules, [627–628](#)

NLRP3 inflammasome, [627–628](#)

*N*-methyl-*D*-aspartate (NMDA), [234–235](#)

*n*-*N*-acetylserotonin (NAS), [822](#)

No touch enucleation, [2557](#)

*Nocardia*, infectious endophthalmitis, [2269](#)

Nomenclature Committee on Cell Death (NCDD), [606](#)

Noncoagulative laser treatment techniques, [2601](#)

Noncoding RNA (ncRNA), [734](#)

Noncollagenous structural proteins, in vitreous, [544](#)

Noncystic peripheral retinal tuft, [559f](#)

Noncystoid edema, [36f](#)

Nondamaging photothermal therapy, [850f–851f](#), [853t](#)

Nondegradable polymers, [833](#)

Nonexpansile concentration of gases, [1959](#)

Nongeographic atrophy

- clinical findings in, [1320](#)
- imaging of, [1324–1327](#)

Nonheritable retinoblastoma, unilateral, [2392–2393](#)

Non-Hodgkin lymphoma, [2667–2668](#), [2667f–2669f](#)

Nonimmune cell compartment, immune regulation by, [628](#)

Noninfectious retinopathy, [1626–1628](#)

Noninfectious uveitis, in pregnancy, [1779](#)

Non-neovascular disease, age-related macular degeneration outcomes after MTS360, [2247](#)

Non-neovascular (dry) AMD, [86–88](#)

- early, [86–87](#), [86f–88f](#)
- late, [87–88](#), [89f–90f](#)

Nonocular toxicity, choroidal metastases and, [2625](#)

Nonparaneoplastic AIR

- clinical manifestations of, [1563](#)
- diagnostic criteria for, [1565t](#)

Nonproliferative diabetic retinopathy, [1061–1090](#), [1092](#), [1092f](#)

- clinical evaluation of, [1063–1070](#)
  - ancillary ocular imaging, [1065–1068](#)
  - duration of diabetes mellitus, [1063](#)
  - dyslipidemia, [1065](#)

- funduscopy lesions of, [1068–1069](#), [1068f–1069f](#)
- hyperglycemia, [1064](#)
- hypertension, [1064–1065](#)
- ophthalmic evaluation, [1065](#)
- other extraocular factors, [1065](#)
- management of, [1075–1085](#)
- natural course of, [1061–1063](#)
  - capillary closure, [1063](#)
  - diabetes mellitus without retinopathy, [1061](#), [1062f](#)
  - diabetic macular edema, [1062–1063](#)
  - microaneurysms, [1061](#), [1062f](#)
  - microvascular remodeling, [1063](#)
  - retinal ischemia, [1063](#)
  - retinal vascular hyperpermeability, [1062](#)
- ocular treatment for, [1082–1084](#), [1083f](#)
- other systemic treatment for, [1084–1085](#)
- Nonproliferative sickle retinopathy, [1206–1209](#)
  - black sunbursts, [1209](#), [1209f](#)
  - iridescent spots, [1209](#), [1209f](#)
  - salmon patch hemorrhages, [1206–1209](#), [1209f](#)
- Nonrandomized prospective study, of small choroidal melanoma, findings from, [2618](#), [2619f](#)
- Nonretinal detachment, primary vitrectomy for, [2026](#)
- Nonrhegmatogenous retinal detachment, [1828–1849](#)
  - in accelerated hypertension, [1833](#)
  - in age-related macular degeneration, [1838f](#)
  - astrocytoma and, [1842](#), [1843f](#)

in bullous retinal detachment, 1829–1830, 1829*f*  
central retinal vein occlusion (CRVO) and, 1834, 1835*f*  
central serous chorioretinopathy and, 1828–1830  
in choroidal hemangioma, 1839–1840, 1839*f*, 1839.e1*f*

## Ocular treatment

for diabetic macular edema, [1076–1082](#)

corticosteroids, [1079–1081](#)

focal/grid laser photocoagulation, [1081–1082](#), [1082t](#)

vascular endothelial growth factor (VEGF) antagonists, [1077–1079](#), [1079f](#)

vitrectomy, [1082](#)

for nonproliferative diabetic retinopathy, [1082–1084](#), [1083f](#)

## Ocular tuberculosis, [1657–1660](#)

differential diagnosis, [1659](#)

pathogenesis, [1659–1660](#)

## Ocular ultrasound, for hypotony maculopathy, [1491](#), [1491f](#)

## Ocular von Hippel-Lindau disease

clinical features of, [2428–2431](#), [2428f–2429f](#), [2431f](#)

pathology of, [2431–2432](#), [2431f](#)

treatment of, [2432–2435](#)

## Oculodermal melanocytosis, [2457–2458](#), [2458f](#)

## Oculodigital sign, [889–890](#)

## Ocusert system, [831–832](#), [836](#)

## OFF cone bipolar cells, [422](#), [422f–423f](#)

## Ofloxacin, [1662t](#)

## Oguchi disease, [257](#), [258f](#), [1007f](#), [1012–1013](#)

electroretinograms, [1013](#), [1013f](#)

## OHR-102, for age-related macular degeneration, [1406–1407](#)

## Older children, retinoblastoma in, [2410–2412](#)

## Older patient, branch retinal vein occlusion in, [1159](#)

## Oligocone trichromacy, [1010](#)

Olivary pretectal nucleus (OPN), 438

Omega-3 fatty acids, AMD and, 1276

ON cone bipolar cells, 422–428, 422*f*

Onchocerciasis, 1695–1696

ONL, [Outer nuclear layer](#); Outer nuclear layer (ONL)

Open-globe injuries, 2082*t*, 2087–2102

- cataract, 2101
- endophthalmitis, 2100–2101
- late complications of penetrating injury, 2101–2102, 2101*f*–2102*f*
- management of intraocular foreign body, 2090–2094, 2091*t*, 2092*f*–2095*f*
- perforating injury, 2095–2096, 2096*f*
- preoperative evaluation of, 2087–2089, 2088*f*–2089*f*
- repair of laceration, 2089–2090, 2091*f*
- retinal detachment, 2096–2100, 2098*f*
- vitreous hemorrhage, 2096–2100, 2098*f*–2099*f*

, Operating microscope injuries, 1750–1752, 1751*f*

Operating room, photothermal retinal injuries in, 1748

Ophthalmia, sympathetic, 1496–1504

- clinical findings of, 1499, 1499*f*
- course and complications in, 1501
- diagnosis of, 1499, 1500*f*–1501*f*
- epidemiology of, 1496
- immunopathology of, 1497–1498, 1497*f*–1498*f*
- pathogenesis of, 1496–1497
- prevention of, 1502
- prognosis of, 1502

therapy for, [1501–1502](#)

Ophthalmic evaluation

- choroidal metastases and, [2622](#)
- of nonproliferative diabetic retinopathy, [1065](#)

Ophthalmic findings, of primary vitreoretinal lymphoma (PVRL), [2676](#), [2676f–2677f](#)

Ophthalmic laser facility, [1752](#)

Ophthalmic oncology, wide-field imaging for, [159–160](#), [159f–160f](#)

Ophthalmic treatment, of primary vitreoretinal lymphoma (PVRL), [2678](#)

Ophthalmic ultrasound, of uveal effusion syndrome, [1487](#), [1487f](#)

Ophthalmodynamometry, of ocular ischemic syndrome, [1235](#)

Ophthalmology, nanomedicine in, [780–810](#)

Ophthalmoscope

- development of, [143](#)
- photochemical retinal injuries from, [1752](#)

Ophthalmoscopy, [176](#), [177f](#)

- adaptive optics scanning laser, retinitis pigmentosa, [881](#)
- drusen characteristics identified with, [1305–1306](#), [1305f–1307f](#)

OPL, [Outer plexiform layer \(OPL\)](#)

OPN, [Olivary pretectal nucleus \(OPN\)](#)

Opportunistic infections, [1626](#)

“Paraneoplastic acquired night blindness”, [2475–2477](#)

Paraneoplastic bilateral diffuse uveal melanocytic proliferations,  
[2509](#)

Paraneoplastic retinopathy, [1567](#)

autoimmune, [894](#)

management of, [2479–2480](#)

Paraneoplastic syndromes, [2474](#)

Paraneoplastic vitelliform maculopathy (PVM), [2478–2479](#), [2479f](#)

Parasitology, of ocular toxocariasis, [1686](#)

Pars plana vitrectomy (PPV), [2115–2121](#)

complete posterior hyaloid separation and, [2116–2117](#), [2116f–](#)  
[2117f](#)

for endogenous endophthalmitis, [1703](#), [1705](#)

incomplete posterior hyaloid separation and, [2117–2119](#), [2117f–](#)  
[2119f](#)

infectious endophthalmitis, [2276–2280](#)

postoperative infection, [2272](#)

preparation of entry sites, [2115](#), [2115f–2116f](#)

for rhegmatogenous retinal detachment, [1854–1855](#)

with subtotal posterior vitreous adhesion, [2119](#), [2119f](#)  
for uveal effusion syndrome, [1490](#)  
vitrectomy, [2116–2120](#), [2116f](#)

Pars plana vitreoretinal surgery, and optical coherence tomography, [167](#)

Pars planitis, [1587](#), [1591](#)

Parylene C scaffolds, [800](#), [800f–801f](#)

Patches, in BDUMP, [2480](#), [2481f](#)

Patchy chorioretinal atrophy, [1429](#), [1430f](#)

Pathologic angiogenesis  
in retinal health and disease, [630–631](#)  
role of, in DR, [631](#)

Pathologic myopia, [1423–1437](#)  
in animal models, [1425–1426](#), [1426f](#)  
epidemiology of, [1423–1424](#)  
histopathology of, [1424–1426](#)  
pathogenesis of, [1424](#)

Pathology Center (Boston, Massachusetts; later Madison, Wisconsin), [2614–2615](#)

Patient education, for neovascular age-related macular degeneration, [1367](#)

Pattern dystrophy, [978–982](#)  
clinical features of, [979–981](#)  
adult-onset foveomacular vitelliform pattern dystrophy, [979–980](#)  
butterfly-shaped pigment dystrophy, [979](#)  
central areolar choroidal dystrophy, [981](#)  
Sjögren's reticular dystrophy of RPE, [980–981](#)

electrophysiology of, 981  
fundus photograph of, 978f–981f  
, pathophysiology of, 981–982  
treatment for, 982

Pattern electroretinography (PERG), 240–242  
neuroprotection and, 812–813

Pattern macular dystrophy, 1003

Pattern scanning laser photocoagulation, 853–854

*Pax2* gene, 376t

*Pax6* gene, 376, 376t, 377f  
*FoxN4* and, 380  
mutations of, 380

PCARP, Posterior column ataxia and retinitis pigmentosa syndrome (PCARP)

PCV, Polypoidal choroidal vasculopathy; Polypoidal choroidal vasculopathy (PCV)

*PDE6* gene, mutations in, 586

PDGF signaling network, 1869

PDS, Port delivery system

“Peak” phase, of fluorescein angiogram, 12

Peanut agglutinin (PNA), retinal adhesion and, 509, 509f–510f

PEDF, Pigment epithelial-derived factor; Pigment epithelium-derived factor

Pediatric retina, wide-field imaging for, 155, 155f

Pediatric retinal vascular diseases, 1246–1267  
newborn screening for, 1263

Pediatric vitreoretinal disorders, surgery for, 2170–2193  
closed globe injury, 2176–2178

- oradialysis, 2176–2177

summary of procedure of, 1949*f*, 1951

surgical technique for, anesthesia for, 1945–1946

for “U” (horseshoe) tears, 2011

utilization of, 1953–1954

and vitrectomy, 1952–1953

*Pneumocystis carinii* choroidopathy, 1642–1643, 1643*f*

Pneumohydraulic exchange, [1640](#)

Polarity, of RPE, [452–454](#), [452f–454f](#), [453t](#)

Polarized sheet, in cell delivery strategies, [2312–2313](#), [2314t](#)

Pole granuloma, posterior, [1687–1688](#), [1688f–1689f](#)

Poliosis, [1505](#)

Polyamidoamine dendrimer, [783–784](#)

Polyarteritis nodosa, [1615–1616](#)

- articular and systemic disease of, [1616](#)
- epidemiology of, [1616](#)
- ocular disease of, [1616](#)
- treatment of, [1616](#)

Polydactyly-obesity-kidney-eye syndrome, [890](#)

Polyethylene glycol (PEG), [783](#), [832–833](#)

Polyethylenimine (PEI), [835](#)

Polylactic-co-glycolic acid (PLGA), [833](#)

Polylysine, [835](#)

Polymerase chain reaction (PCR), for ARN syndrome, [1713–1714](#)

Polymer-drug conjugates, [783](#)

Polymeric nanoparticles, [786](#)

Polymethyl methacrylate (PMMA), [2561–2562](#)

Polymorphisms, [717](#)

Polymyositis, [1611–1612](#)

- articular and systemic disease of, [1611](#)
- epidemiology of, [1611](#), [1611b](#)
- ocular disease of, [1611](#)
- treatment of, [1611–1612](#)
  - of ocular disease, [1612](#)

- of systemic disease, [1611–1612](#)
- Polyol pathway, [584](#)
- Polyplexes, [789](#)
- Polypoidal choroidal vasculopathy (PCV), [56–59](#), [63f](#), [92–93](#), [1458–1464](#), [1467–1468](#)
  - classification of, [1461](#)
  - clinical features of, [1459–1461](#)
    - angiographic features in, [1461](#)
    - clinical findings in, [1459](#), [1460f–1461f](#), [1461b](#)
    - demographics in, [1459–1461](#)
  - differential diagnosis of, [1461–1462](#)
    - central serous chorioretinopathy in, [1462](#)
    - neovascular age-related macular degeneration in, [1461–1462](#)
  - idiopathic, [707](#)
  - pathogenesis of, [1458–1459](#)
  - retinal detachment in, [1838–1839](#), [1838f](#), [1838.e1f](#)
  - treatment of, [1462–1463](#)
    - anti-VEGF therapy for, [1463](#)
    - combination therapy for, [1463](#)
    - photodynamic therapy in, [1463](#)
    - thermal laser photocoagulation in, [1462–1463](#)
- Pomerantzeff camera, [144](#)
- Pooled findings from Ranibizumab trials, [1809](#)
- “Popcorn”, [1247–1248](#)
- Porins, [722](#)
- Porous scaffolds, [799–800](#)
- Port delivery system (PDS), [836](#)

for age-related macular degeneration, [1403–1404](#)

Portable Eye Examination Kit (PEEK), [178–179](#)

Portal color sort test (PCST), [337](#)

Posaconazole, for endogenous endophthalmitis, [1704](#), [1704b](#)

Positioning spots, [1965–1966](#)

Positioning the patient, in fluorescein angiography, [6](#), [6.e1f](#)

Positive emission tomography scan (PET), sarcoidosis and, [1574](#)

Positron emission tomography/computed tomography (PET/CT), [2609](#), [2610f](#)

Posterior ciliary artery (PCA), [52f](#)  
in fluorescein angiography, [7–8](#)  
in fundus, [10](#)

Posterior column ataxia and retinitis pigmentosa syndrome (PCARP), [869f](#)

Posterior hyaloid detachment, macular hole and, [2220–2221](#), [2220f](#)  
, Posterior penetrating trauma, vitreoretinal effects of, [569](#), [571f](#)

Posterior pole granuloma, [1687–1688](#), [1688f–1689f](#)

Posterior pole-degenerative remodeling, [557](#), [562f](#)

Posterior scleritis, retinal detachment in, [1837](#)

Posterior segment disease, [1576–1578](#)

Posterior segment involvement, of SCD, [1206](#)

Posterior staphyloma, [1426](#), [1427f–1428f](#)

Posterior subcapsular cataract (PSC), [2587](#)

Posterior uveal melanoma  
counseling, in patient, [2558](#)  
enucleation, [2557](#)  
environmental factors of, [2518–2519](#)  
epidemiology of, [2515–2522](#)

- general considerations, [2555–2556](#)
- genetic testing, [2557](#)
- globe-conserving therapies for, [2523–2524](#)
- hormones and reproductive factors of, [2517–2518](#)
- host factors of, [2515–2517](#)
  - age, [2515–2516](#)
  - ancestral origin, [2516](#)
  - cancer genetics, [2516–2517](#)
  - cutaneous nevi, [2517](#)
  - ocular nevi, [2517](#)
  - race, [2516](#)
  - sex, [2515–2516](#)
- incidence of, [2515](#), [2516t](#)
- introduction to, [2515](#)
- laser photocoagulation, [2556](#)
- local resection, [2557](#)
- metastasis and
  - after enucleation, [2526](#)
  - clinical prognostic indicators for, [2527](#)
  - histopathologic prognostic indicators for, [2527–2528](#)
  - histopathology of, [2527–2528](#)
  - immunogenetics of, [2527–2528](#)
  - local treatment failure and prognosis, [2525](#)
  - molecular prognostic indicators for, [2528–2529](#)
  - and survival, [2525](#)
  - systemic prognosis for, [2524–2525](#)
- nonradiation therapy for, [2524](#)

- orbital exenteration, [2557](#)
- overview of management of, [2555–2560](#)
- periodic observation, [2556](#), [2556t](#)
- photodynamic therapy, [2556](#)
- prognosis of, [2523–2532](#)
  - after enucleation, [2525–2526](#)
  - improving, with early treatment, [2529](#)
  - visual, and ocular morbidity, [2526–2527](#), [2526f](#)
- radiation therapy and, [2523–2525](#)
- radiotherapy, [2556–2557](#)
- silicone oil and, [2524](#)
- surgery in, [2524](#)
- systemic metastasis, management of, [2557–2558](#)
- systemic prognosis for metastasis and death, [2524–2525](#)
- transpupillary thermotherapy, [2556](#)

#### Posterior uveitis

- clinical trials on, [1816–1817](#)
- other trials for, [1816–1817](#)

#### Posterior vitreous cortex (PVC), [545–547](#), [550f](#), [1916](#)

- truncation, [1923f](#)

#### Posterior vitreous detachment (PVD), [557–562](#), [750](#), [1667](#), [2358](#)

- anomalous, [562–568](#), [563f](#)
  - macular effects of, [565–568](#)
  - optic disc effects of, [568](#)
  - vitreous effects of, [562](#), [564f](#)

- early stages of, [2214](#), [2215f](#)

- epidemiology of, [557–562](#)

in epiretinal membrane, [2195](#), [2196f](#)  
to impending macular hole, pathogenesis of, [2214–2215](#)  
induction of  
    in high myopia, [2369](#)  
    in retinal detachment, [2369](#)  
symptomatic, [562](#)

Postexposure prophylaxis (PEP), [1624](#)

Postoperative visualization, intraocular gas and, [1959–1960](#)

Post-organ transplantation, retinal detachment and, [1846–1847](#)

Postsurgical exudative retinal detachment, [1845–1847](#), [1846f](#)

Postvitrectomy gas exchange, intraocular gas in, [1965](#), [1965f](#)

Potassium iodate, retinal toxicity from, [1727–1728](#)

*POU domain transcriptional regulators*, [384](#)

Povidone iodine, [1891](#)

PPRCA, [Pigmented paravenous retinochoroidal atrophy \(PPRCA\)](#)

PR, [Pneumatic retinopexy](#)

Pramlintide, for diabetes mellitus, [1058](#)

pRb protein, [2379](#)

*Prdm1/Blimp* gene, [380](#)

Preclinical diabetic retinopathy (PCDR), [673](#)

Prednisone  
    in paraneoplastic retinopathy, [2480](#)  
    for sympathetic ophthalmia, [1501](#)  
    systemic, for serpiginous choroiditis, [1529](#)

Preeclampsia, [1771](#)  
    amniotic fluid embolism in, [1774](#), [1775f](#)  
    central serous chorioretinopathy in, [1773](#)

choroidopathy in, [1772–1773](#)  
cortical blindness in, [1773](#)  
cortical vision loss in, [1773](#)  
diabetic retinopathy and, [1779](#)  
disseminated intravascular coagulopathy in, [1774](#)  
intracranial hemorrhages in, [1773](#)  
occlusive vascular disorders in, [1773](#)  
retinal artery occlusion in, [1773–1774](#)  
retinal vein occlusion in, [1774](#)  
retinopathy in, [1771–1772](#)  
Susac syndrome in, [1774](#)  
thrombotic thrombocytopenic purpura in, [1774](#)

Pre-enucleation radiotherapy (PERT), [2557](#)

Preferential hyperacuity perimetry (PHP), [352](#), [1413](#)

Pregnancy

- diabetic macular edema and, [1778](#)
- diagnostic testing and therapy for, [1779–1780](#)
  - anti-VEGF therapy as, [1780](#)
  - photodynamic therapy as, [1780](#)
- diseases related to, [1771–1785](#)
- preexisting conditions in, [1776–1779](#)
  - diabetic retinopathy as, [1776–1779](#)
  - noninfectious uveitis as, [1779](#)
  - toxoplasmic retinochoroiditis, [1779](#)
- retinal and choroidal disorders in, [1771–1776](#)

Pregnancy-induced hypertension, retinal detachment in, [1833](#), [1834f](#)

Preimplantation genetic diagnosis (PGD), for retinoblastoma, [2378](#)

Preinjection fluorescence, [19](#), [22](#)

Premacular membranes, in periretinal cell proliferation, [569–571](#), [571f–573f](#)

Premacular vitreous cortex, contraction of, [2214](#)

Prematurity

- history of, [1255](#)
- retinopathy of, [302](#), [302f](#)

Pre-mRNA splicing, abnormal, retinitis pigmentosa and, [905](#)

Preruleation radiation, for large choroidal melanoma, findings from, [2617–2618](#)

- complications in, [2617–2618](#)
- participants in, [2614t](#), [2617](#)
- survival estimates in, [2617](#), [2618f](#)

Preparation, in choroidal melanoma, [2592](#)

Pre-plus disease, [1253](#)

Preprocessing, in retinal image analysis, [202–203](#)

Preretinal area, in fluorescein angiography, [9](#)

Preretinal hemorrhage, causing hypofluorescent blockage, [15f](#)

Preretinal infiltrates, [2662](#)

Pressure gradient, as mechanical factors, [704](#)

Presumed ocular histoplasmosis syndrome (POHS), [1468](#), [1694–1695](#)

- wide-field imaging of, [162f](#)

Primary brachytherapy, for retinoblastoma, [2400–2401](#)

Primary chemotherapy, tumor regression patterns following, [2377t](#)

Primary full-thickness macular hole, epidemiology and risk factors for, [2213–2214](#)

Primary immune thrombocytopenia (ITP), [1241](#)

Primary intraocular lymphoma (PIOL), 2675  
ocular syphilis *vs.*, 1674*t*  
retinal detachment in, 1841–1842, 1842*f*

Primary intravenous chemotherapy, for intraocular retinoblastoma, 2394

Primary retinal vasculitis, 1666

Primary rod pathway, 426*f*  
utilizes rod bipolar cells, 424

Primary systemic vasculitis, 1612–1614  
adjuvant therapy for, 1613–1614  
aims of therapy for, 1613–1614  
alternative approaches to therapy in, 1614  
classification of, 1613*b*  
induction stage in, 1613, 1614*t*  
maintenance stage in, 1613  
progression and prognosis of, 1612–1613  
treatment of relapse in, 1614

Primary vitrectomy, in rhegmatogenous retinal detachment, 1933–1942  
anesthesia for, 1934  
complications of, 1939–1940  
core vitrectomy in, 1935, 1936*f*  
with encircling buckling, 1936  
fluid-air exchange in, 1936  
patient selection for, 1934  
peripheral vitrectomy in, 1935–1936  
perspective for, 1940  
with phacoemulsification and intraocular lens implantation, 1936

photocoagulation/ cryopexy of the retinal tear in, 1936  
ports through the pars plana in, 1935  
positioning after surgery in, 1936  
principles of, 1934  
prognostic factors of, 1938–1939, 1939*f*–1940*f*  
, surgical outcomes of, 1937–1938, 1938*t*–1939*t*  
surgical techniques for, 1934–1937, 1935*f*  
sutureless microincision, 1936–1937, 1937*f*, 1938*t*  
tamponade in, 1936

Primary vitreoretinal lymphoma (PVRL), 2675–2681  
clinical findings of, 2676–2677  
definition of, 2675  
diagnosis of, 2677–2678  
differential diagnosis of, 2678  
epidemiology of, 2675  
etiology of, 2675–2676  
pathogenesis of, 2675–2676  
prognosis in, 2679  
treatment of, 2678–2679

Primate cones, 414*f*

Primate fovea, 381–382  
development of, 384

Primate retina, 409*f*, 424

Primitive neuroectodermal tumor (PNET), 2375–2376

Prodromal phase, of TTP, 1241

Progenitor cells, retinal, 765

Progressive bifocal chorioretinal atrophy, 999

Progressive outer retinal necrosis (PORN), 1642  
in leukemia, 2666

“Progressive outer retinal necrosis syndrome”, 1713

Progressive rhegmatogenous retinal detachment (RRD), associated with retinoschisis, 1853–1855, 1854*f*

Proliferation, due to drainage retinotomy, 2056

Proliferative diabetic retinopathy (PDR), 100, 100*f*, 1091–1121, 2107–2134, 2362–2363, 2363*f*

absence of, with diabetes of extreme duration, 1103

antiangiogenic therapies for, 1115–1116

blood glucose control and, 1103

cataract and, 2107–2108

combined tractional-rhegmatogenous retinal detachments in, 1824

complications, 2122–2124

intraoperative, 2122–2123

postoperative, 2123–2124

diabetes and

of extreme duration, 1103

type and duration of, 1102, 1102*f*, 1102*t*

Diabetic Retinopathy Vitrectomy Study on, 1102, 1102*t*, 1111*f*

early laser trials for, 1105

early treatment Diabetic Retinopathy Study on, 1109–1111, 1110*f*, 1110*t*

evidence-based trials and, 2124–2125

fibrovascular proliferation and, 1098–1099

high-risk retinal neovascularization, 2108–2109

fibrovascular proliferations, 2108, 2108*f*

vitreous hemorrhage, 2108–2109, 2109*f*  
indications and timing of, 2107–2111  
informed consent in, 2111  
involutional or “quiescent”, 1099–1102  
macular traction and macular edema, 2109  
management of, 1104–1111  
natural course of, 1094–1102  
neovascular glaucoma, 2110–2111  
new vessels in  
    development and proliferation of, 1095–1098, 1095*f*–1097*f*  
    direct (local) treatment of, 1112, 1113*f*  
    preretinal, origin and early recognition of, 1092–1094, 1092*f*–  
    1093*f*  
    regression of, after initial photocoagulation, 1113–1114, 1114*t*  
optical coherence tomography for, 172  
panretinal, photocoagulation for, 1106–1109, 1106*f*, 1106*t*–1107*t*,  
1108*f*, 1109*t*, 1111  
    complications of, 1114–1115, 1115*b*  
    distribution and strength of, 1112  
    treatment protocol for, 1112*t*  
    wavelength of, 1113  
pars plana vitrectomy, 2115–2121  
pathogenesis of, 1092  
pattern scanning laser delivery systems and, 1112–1113  
peripheral diabetic retinal lesions and, 1104  
photocoagulation and, 2120  
pituitary ablation for, 1105  
postoperative care, 2121–2122

preoperative evaluation in, [2111](#)  
retinal detachment, [2109–2110](#)  
retinal distortion in, [1099](#), [1099f–1101f](#)

Retinal arteriolar constriction, 1771–1772

Retinal artery occlusions, 1136–1150

- branch, 1143, 1143f
- central, 1136–1142
  - ancillary studies of, 1139
  - clinical features of, 1136–1139, 1137f–1139f
  - epidemiology of, 1136
  - evaluation of, 1140–1141
  - systemic associations of, 1139–1140, 1141b
  - treatment for, 1142
- cilioretinal, 1143–1144
- combined retinal vein and, 1144–1145, 1144f–1145f
- in pregnancy, 1773–1774

Retinal astrocytes, 467f, 470–471

Retinal atlas, 209–212, 211f–213f

Retinal barrier, 703

Retinal biopsy, 2057

for diagnostic vitrectomy, [2289](#)  
transvitreal, [2302–2303](#)  
    case studies, [2303b](#), [2303f–2304f](#)  
    histologic technique, [2303](#)  
    results, [2303](#)  
    surgical technique, [2302](#), [2302f](#)

Retinal blood flow, non-Doppler assessment of, [183](#), [184f](#)

Retinal blood vessels, interface along, [551–552](#), [554f](#)

Retinal bone-spicule pigmentation, peripheral, [889](#)

Retinal branch vein occlusion, [21f](#)

Retinal break, [1821](#), [1891](#), [1891f](#)  
    in anomalous posterior vitreous detachment, [562–565](#), [564f](#)  
    retinoschisis with, [1852–1853](#), [1852f–1853f](#)

Retinal cancer  
    bilateral diffuse uveal melanocytic proliferation (BDUMP), [2480](#),  
        [2481f](#)  
    cancer-associated retinopathy (CAR) syndrome, [2474–2475](#), [2474f](#),  
        [2476f–2478f](#)  
    introduction to, [2474](#)  
    melanoma-associated retinopathy (MAR) syndrome, [2475–2477](#)  
    paraneoplastic retinopathy, management of, [2479–2480](#)  
    paraneoplastic vitelliform maculopathy, [2478–2479](#), [2479f](#)  
    remote effects of, [2474–2483](#)

Retinal capillary hemangioblastoma, [Retinal hemangioblastoma \(RH\)](#)

Retinal capillary hemangioma, [Retinal hemangioblastoma \(RH\)](#)

Retinal capillary nonperfusion, in ocular ischemic syndrome, [1233](#),  
[1233.e1f](#)

## Retinal cavernous hemangioma

- ancillary studies for, [2423](#), [2423f](#)
- clinical findings in, [2421–2422](#), [2421f–2422f](#)
- differential diagnosis in, [2422–2423](#)
- genetics in, [2425](#)
- natural history of, [2423](#)
- pathology of, [2424](#), [2424f](#)
- systemic and familial involvement in, [2424–2425](#), [2425f](#)
- treatment of, [2424](#)

## Retinal cavernous hemangiomatosis, [2454–2455](#), [2454f](#)

## Retinal cells, classification of, [412–439](#)

- amacrine cells, [428–434](#), [428f](#)
- bipolar cell function, [420–422](#)
- ON cone bipolar cells, [422–428](#), [422f](#)
- feedback mechanism, [418–419](#)
- ganglion cells, [434–439](#)
- horizontal cell function, [418–420](#)
- OFF cone bipolar cells, [422](#), [422f–423f](#)
- photoreceptors, [412–417](#)
- second-order neurons, [417–418](#)

## Retinal changes, after MTS360, [2250](#)

## , Retinal CMV infection

- screening techniques for, [1630–1631](#)
- treatment strategies in, [1634–1635](#)
  - combination therapies, [1634–1635](#)

## Retinal contraction, retinectomy and

- circumferential, [2061–2063](#), [2064f](#)

due to proliferative vitreoretinopathy (PVR), [2061](#)  
focal or diffuse, [2061–2063](#), [2063f](#)  
intrinsic, [2063](#)  
surgical technique for, [2061](#)

Retinal cotton-wool spot, [1627](#), [1627f](#)

Retinal degeneration

- animal models of, [2321](#)
- autosomal dominant, wide-field imaging for, [158f](#)

Retinal degeneration slow (*Rds*) gene, [789](#)

Retinal detachment, [613–614](#), [1255](#), [1260](#), [1772](#), [1772f](#), [2135](#), [2596–2597](#), [2621](#)

- acute, [281–295](#), [292f](#)
- animal models for study, limitations of, [689–690](#)
- in ARN syndrome, [1709](#), [1711f](#), [1715](#)
- associated with choroidal coloboma, [1980](#)
- in asymptomatic eyes without high-risk factors, [2020–2021](#)
  - lattice degeneration and vitreoretinal precursors of retinal breaks in, [2020f](#)
  - vitreoretinal precursors of retinal breaks in, [2020–2021](#)
- in asymptomatic nonfellow eyes with high-risk factors, [2021](#)
- in asymptomatic patients with retinal detachment in the fellow eye, [2021–2025](#)
  - asymptomatic aphakic and pseudophakic fellow eyes in, [2025](#)
  - phakic fellow eyes in, [2022–2025](#)
  - retinal breaks in asymptomatic aphakic and pseudophakic fellow eyes in, precursors of, [2023f](#), [2025](#), [2025t](#)
  - retinal breaks in phakic fellow eyes in, precursors of, [2022](#), [2022t](#)
- asymptomatic retinal breaks and, [2021](#)

cellular changes in, response to, [690–697](#)  
chronic, [295–296](#), [295f–298f](#)  
classification of, [1252f](#), [1254](#)  
closed funnel configuration of, [2164f](#)  
closed-globe injuries, [2087](#)  
combined tractional and rhegmatogenous, [1823–1824](#), [1824f](#)  
definition of, [703](#)  
ERM surgery and, [2200](#)  
ETROP study in, [1260](#)  
evidence-based trials and, [2126](#)  
exudative, [707](#)  
    and hemorrhagic, [1825](#)  
macular hole and, [2225](#)  
major types of, [1821](#)  
occurrence of, [705](#)  
open funnel, [2163f](#)  
open-globe injuries, [2096–2100](#), [2098f](#)  
optical coherence tomography for, [172](#)  
other factors related to, [1254–1255](#)  
partially closed, [2163f](#)  
pathogenetic mechanisms of, [1821–1827](#)  
pediatric, complicated, [1980](#)  
    from peripheral retinal breaks, [2147](#)  
    persistent inflammatory serous, [2141](#)  
    posterior ROP, anti-VEGF therapy for, [1260](#)  
prevention of, [2017–2030](#)  
proliferative diabetic retinopathy and, [2109–2110](#)

with proliferative vitreoretinopathy, 1978–1979  
PVD in, 2369  
recurrent, silicone oil (SO) and, 1987  
retinal hypoxia and, 497  
retinoschisis and, comparison of, 1851*t*  
rhegmatogenous, 1821–1823, 1821*f*–1822*f*, 1824*f*, 2135–2145  
risk factors for, 2018, 2018*t*  
scleral buckling for, 1964–1965  
serous, [Serous retinal detachment](#)  
subretinal SF<sub>6</sub> gas after, 2374  
in symptomatic eyes, 2017*f*, 2018–2020  
    horseshoe-shaped tears and, 2018–2019, 2019*f*, 2019*t*  
    retinal holes and precursors of retinal detachment in, 2019–  
        2020  
    retinal tears in, 2019  
    round tears in, 2019, 2019*f*  
    tears unassociated with persistent vitreoretinal traction, 2019–  
        2020  
    tears with persistent vitreoretinal traction in, 2018–2019  
tractional, 1823  
traumatic, 1762–1764, 1762*f*  
treatment methods for, 2026–2028  
    cryotherapy in, 2026  
    laser photocoagulation in, 2026–2027  
    surgical techniques for, 2027–2028  
visual field and, 366  
vitrectomy for, 1962, 1963*f*  
water movement impairment in, 705

## Retinal detachment repair

due to retinal dialyses, [2009–2010](#)

macular translocation and, [2250](#)

optimal procedures for, [2007–2016](#)

practice, variations in, [2014](#)

retinal dialysis and, [2009–2010](#)

round hole, [2007–2009](#), [2008f](#)

“U” (horseshoe) tears, secondary to, [2010–2014](#)

vitrectomy and, [2009](#)

## Retinal detachment surgery

PVR and, [2031–2032](#), [2031f–2032f](#)

recurrent, [2032–2033](#), [2033f](#)

rhegmatogenous, [2033–2034](#), [2033f](#)

B-scan ultrasound with, [2034f](#)

## Retinal development

chromatin remodeling complexes in, [736](#)

histone acetylation in, [736](#)

histone methylation in, [735–736](#)

microRNAs in, [736](#)

## Retinal dialysis, [1762–1763](#), [1763f](#)

conservative management of, [2009](#)

detachment due to, [2009–2010](#)

natural history of, [2009](#)

treatment of, [2010](#)

laser demarcation for, [2010](#)

scleral buckling for, [2010](#)

## Retinal disease

associations of haplogroups with, [725–726](#)  
constitutive phototransduction and, [400–401](#)  
epigenetic mechanisms of, [736–740](#)  
    in age-related macular degeneration, [738](#)  
    choroidal neovascularization, [740](#)  
    diabetic retinopathy, [739–740](#), [741f](#)  
    DNA methylation, [737](#)  
    histone acetylation/deacetylation, [737–738](#)  
    in retinal angiogenesis, [739](#)  
    in retinal fibrosis, [736–737](#)  
    in retinitis pigmentosa, [738](#)  
    in retinoblastoma, [738–739](#)  
    treatment of retinal disease with epigenetic-modifying drug,  
        [741–742](#)  
    in uveal melanomas, [739](#)  
ER stress in, [596–605](#), [600f](#)  
evaluated in human clinical trials, [753–755](#)  
genetic mechanisms of, [711–721](#)  
    genetic testing methods, [719–720](#)  
    human genetics and, basic concepts of, [711–716](#)  
    human genome, [716–719](#)  
human clinical trials using stem cells for treatment of, [773–775](#)  
invasive diagnostic techniques for, [1646–1647](#)  
mitochondria as target for, [728–729](#)  
mitochondrial genetics of, [722–732](#)  
    DNA, [722–723](#)  
    electron leakage and ROS formation, [725](#)

- function, [723](#)
- influences of mtDNA on cell function, [725–729](#)
- localization of mitochondria within retina and optic nerve, [725](#), [725f](#)
- origins, [722](#)
- structure, [722](#), [723f](#)
- in pregnancy, [1771–1776](#)
  - and preeclampsia, eclampsia, and “HELLP” syndrome, [1771](#)
- recent maternally transmitted mtDNA mutations associated with, [726](#)
- somatic mtDNA variations associated with, [726–728](#)
  - epigenetics and mtDNA, [728](#)
  - mechanisms of mtDNA damage, [726–728](#)
  - mtDNA damage and AMD, [728](#)
- stem cells as therapeutics to treat, [763](#)
- transducin defects and, [401](#)
- Retinal displacement, anterior, retinectomy and, [2063–2065](#), [2065f–2067f](#)
- Retinal dystrophies, [614](#)
  - photoreceptor transplantation in, [2321](#)
  - visual field and, [353](#)
  - wide-field imaging for, [157–159](#), [157f–158f](#)
- Retinal emboli, [496–497](#)
- Retinal fibrosis, epigenetic factors in, [736–737](#)
- Retinal folds
  - from drug toxicity, [1734](#), [1736f](#)
  - in hypotony maculopathy, [1493–1494](#), [1493f](#)
- Retinal ganglion cell glaucomatous disease, [811–813](#)

Retinal ganglion cells, [380–381](#), [1787](#)

Retinal ganglion cells (RGC) loss, [610–611](#)

- glaucoma and, [611](#)
- as neuroprotective agent, [615t](#)

Retinal gene therapy

- current status of, [753–755](#)
  - CNV using AdPEDF, [753–754](#)
  - encapsulated cell therapy, [754](#)
  - retinoblastoma, [753](#)
- , generic strategies for reversing blindness in “dead” retinas, [758](#)
- genotyping issues, [757](#)
- history of, [751–753](#)
- outcome measures in human clinical trials, [756](#), [756f](#)
- plasticity of visual system, [756–757](#)
- safety/efficacy/stability issues, [755–756](#)
- state of art of, [758](#)
- studies in progress, [754–755](#)
  - choroideremia (CHM), gene augmentation therapy for, [754–755](#)
  - CNV and AAV-sFLT, [754](#)
  - CNV and lentivirus-mediated delivery of angiostatin and endostatin, [754](#)
  - Leber congenital amaurosis, gene augmentation therapy for, [754](#)
  - Leber hereditary optic neuropathy (LHON), gene augmentation therapy for, [755](#)
  - X-linked juvenile retinoschisis (XLRS), gene augmentation therapy for, [754](#)
- treatment *versus* cure, [757–758](#)

window of opportunity, 756

## Retinal glia

cell biology of, 466–487, 467f

Müller glial cells, 467f, 471–484, 472f–473f

CO<sub>2</sub>, removal of, 476f, 480

edema development and resolution, contribution to, 469f, 477f–479f, 481–483, 481f–482f

extracellular space volume, regulation of, 469f, 478f, 482f, 483

glial glutamate uptake, retinal degeneration and, 469f, 474–475, 475f–477f, 479f

gliosis, 468f–469f, 476f–479f, 481f, 483–484

glutamate-glutamine cycle, 475–480, 475f

light guidance, 472f–473f, 474

mechanical stress, responses to, 468f–469f, 476f–477f, 479f, 482f, 483

neurotransmitter uptake, regulation of synaptic activity by, 474, 475f–476f

neurovascular coupling mediation, 469f, 476f–477f, 483

pH, regulation of, 476f, 480

photoreceptor function, glial support to, 474

photoreceptors and neurons, trophic and antioxidative support to, 475f, 480

spatial potassium buffering, 469f, 477f–479f, 480–481

stem cells, 479f, 484

water clearance, 469f, 478f, 481

retinal astrocytes, 467f, 470–471

activation of, 471

in aging retina, 470

- degeneration of, [471](#)
- in diseased retina, [470–471](#)
- malfunction of, [471](#)
- retinal microglia, [466–470](#), [467f–469f](#)
  - activation, [467](#), [468f–469f](#)
  - in aging retina, [468f](#), [470](#)
  - neuronal degeneration, contribution to, [467–470](#), [469f](#)
  - neuronal survival, contribution to, [470](#)
  - resting, [466](#), [468f–469f](#)
- Retinal grafts, [2322](#)
- Retinal guanylyl cyclase (RetGC), Ca<sup>2+</sup>-feedback to, [395](#), [395f](#)
- Retinal health and disease
  - age-related macular degeneration and, [631–633](#)
  - aging influence in, [628–629](#)
  - erosion of, in absence of infectious disease, [629](#)
  - immune responses in, [625–637](#)
  - inflammation in, [625–637](#)
  - maintenance of, innate defences in, [626–629](#), [626f](#)
  - nonuveitic disease and, [629–630](#)
  - pathologic angiogenesis in, [630–631](#)
  - persistent immune activation and, [628](#)
  - vascular regulation and, [630–631](#)
- Retinal hemangioblastoma (RH), [2427–2437](#)
  - clinical features of, [2428](#), [2428f](#)
  - extrapapillary
    - ablative treatment of, [2432–2434](#), [2434f](#)
    - surgical excision of, [2434](#)

- fully developed, [2429f](#)
- juxtapaxillary, treatment of, [2434](#)
- multiple, [2429f](#)
- pathology of, [2431–2432](#), [2431f](#)
- peripheral, [2429f](#)

Retinal hemorrhage, [1628f](#)

- ocular ischemic syndrome and, [1229](#), [1230f](#), [1229.e1f](#)

Retinal hole, water movement impairment and, [705](#)

“Retinal hypovascularopathies”, [1189](#)

Retinal hypoxia, [1666](#)

- diabetic retinopathy and, [495–496](#)
- ocular ischemic syndrome and, [497](#)
- retinal detachment and, [497](#)
- retinal vein occlusion (RVO) and, [496–497](#)
- sickle-cell disease and, [497](#)
- vascular permeability and, [497](#)

Retinal image compression, [201](#)

Retinal image quantities, [201](#)

Retinal images

- grading of, [1132–1133](#)
  - arbitration, [1132](#)
  - pathways of, [1132](#)
  - reading personnel on, [1132](#)
- ungradable, handling of, [1132–1133](#)

Retinal imaging

- magnetic resonance imaging and, [190](#), [190f](#)
- wide-field imaging for, [143](#)

Retinal incarceration, retinectomy for, [2059–2061](#), [2061f](#)  
surgical technique for, [2060–2061](#), [2060f](#), [2062f](#)

Retinal infiltrates, [2662](#)

Retinal inflammatory diseases, [893](#)

## Retinal ischemia

consequences of, [497](#)

nonproliferative diabetic retinopathy and, [1063](#)

retinal oxygenation and, [490](#)

Retinal laser photocoagulation, for radiation retinopathy, [1223–1224](#)

Retinal lattice, [561f](#)

Retinal layer detection, [214–215](#)

Retinal layer thickness analysis, [215](#)

Retinal leakage, in transmitted fluorescence, [34](#), [35f–37f](#)

## Retinal lesions

anastomosis, [1354](#)

detection of, [207–209](#), [207f–208f](#), [210f](#), [216–217](#), [217f](#)

healing of, [852f](#), [853](#)

peripheral diabetic, proliferative diabetic retinopathy and, [1104](#)

Retinal light exposure, [1746](#)

Retinal lymphoma, in HIV-positive patient, [1647f](#)

Retinal macroaneurysms, [1151–1154](#)

clinical description of, [1151](#), [1151f–1152f](#)

description of, [1151](#)

diagnosis of, [1152](#)

differential diagnoses of, [1153](#)

natural course and treatment of, [1152–1153](#), [1153f](#)

Retinal manifestations, of TSC, [2440–2441](#), [2440f–2441f](#)

Retinal mass, retinotomy and, [2057](#)

Retinal maturation, [384](#)

Retinal metastases, [2461–2473](#)

angiogenesis and, [2462](#)

- cascade, [2461](#)
- clinical findings in, [2462–2468](#)
- demographics of, [2462](#)
- diagnostic evaluation of, [2469–2471](#), [2469f–2470f](#)
- differential diagnosis of, [2468](#), [2468f–2469f](#)
- dissociation, invasion, and intravasation in, [2461](#)
- extravasation and, [2462](#)
- hematogenous dissemination and, [2461](#)
- introduction to, [2461–2462](#)
- prognosis, [2471](#)
- review of case reports and, [2462–2471](#), [2463t–2466t](#)
- signs of, [2462–2468](#), [2462f](#), [2467f](#)
- symptoms of, [2462](#), [2463t–2466t](#)
- treatment of, [2470–2471](#)

Retinal microglia, [466–470](#), [467f–469f](#)

Retinal necrosis

- acute, [2140f](#), [2142–2143](#), [2143f](#)
- rhegmatogenous retinal detachment (RRD) with, [2141–2142](#)

Retinal neovascularization

- branch retinal vein occlusion and, [1160](#), [1160f](#)
- circumscribed choroidal hemangioma, [2638](#)
- dominantly inherited peripheral, [947–948](#)
- peripheral, [1577–1578](#)
- retinectomy and, [2069](#)
- secondary stage of, [1247–1248](#), [1247f–1248f](#), [1247.e2f](#)

Retinal nerve fiber layer (RNFL), [182](#)

Retinal neurons

- classification of, [412](#)
  - techniques to label and visualize, [410–412](#)
- Retinal nuclear receptor (NR2E3)-related diseases, [946–947](#)
- clinical findings of, [946–947](#)
  - differential diagnosis of, [947](#)
  - electrophysiology of, [947](#)
  - general features of, [946](#)
  - management of, [947](#)
  - ocular features of, [946](#), [946f](#)
  - visual psychophysics of, [947](#)
- Retinal operculum, in vitreous hemorrhages, [280](#)
- Retinal oxygenation, [488–503](#)
- assessment of, [185–188](#)
  - hyperoxia and, [490](#)
  - hypoxia and, [490–495](#)
    - bone marrow-derived progenitor cells (BMPC) and vascular repair in, [493–494](#)
    - , disease-associated BMPC dysfunction in, [494–495](#)
    - etiology of, [495–497](#)
    - HIF deficiency in, [492](#)
    - HIF-activated genes in, [492](#)
    - hypoxia-inducible factor (HIF) in, [491–492](#)
    - VEGF in, [492–493](#), [494f](#)
  - normoxia and, [490](#), [490f](#)
  - retinal ischemia and, [490](#)
- Retinal periphlebitis, [1666](#)
- Retinal phototoxicity, [1748–1749](#)

Retinal pigment damage, due to retinectomy, 2069

Retinal pigment epithelium detachment, 89–92, 91*f*

Retinal pigment epithelium (RPE), 46, 70*f*, 120–121, 181, 181*f*, 378, 626*f*, 628, 667–668, 670*f*, 833, 1287–1288, 1294–1296, 2546

- in age-related macular degeneration, 2254–2265, 2256*t*
- aging and senescence of, 643
- alterations in, 1072, 1075*f*, 1322–1323
- anatomy and histology, 451–456
  - cellular junctions, 454–455, 454*f*
  - cytoskeleton, 455
  - heterogeneity and polarity, 452–454, 452*f*–454*f*, 453*t*
  - synthesis and remodeling, role of, 455–456

Bruch's membrane and, 522

cell biology of, 451–465

cell proliferation, 690–691, 691*b*, 691*f*

central serous detachment, 703–710

changes after MTS360, 2250

changes in, 2662, 2663*f*

choroid translocation and stem cells, 2261–2263

coagulopathies and, 1241

complex, 79–80

component of, 229–230

deformation algorithm, 81, 81*f*

degenerative patterns, 139*f*

detachment and reattachment, cellular effects of, 689–702

detachments, 1285, 1346, 1346*f*–1347*f*

- in age-related macular degeneration, 1352–1353

disruption of, drug toxicity in, 1719–1728  
fibrotic reaction to, 2262*f*  
in fluorescein angiography, 9  
hypertrophy of, 18*f*  
as neuroprotective agent, 615*t*  
oxidative injury to, 585  
pathologic myopia and, 1424–1425  
photoreceptor interface and, 690–691, 690*f*–691*f*  
photoreceptors and, 1301–1304  
in proliferative vitreoretinopathy, 572, 575*f*  
retina and, 2508  
specialized function of, 456–459  
    cytokines and growth factors, secretion of, 459, 460*t*  
    immune privilege, 459  
    immune response, 459  
    light, absorption of, 454*f*, 456  
    maintaining avascular outer retina, role in, 458–459  
    nutrients, ions, and water, transport of, 459  
    outer segments, phagocytosis of, 456–457, 456*f*  
    oxidative stress, protection from, 457–458, 458*f*  
    visual cycle, role in, 457, 457*f*  
subcellular components and mobility of, 510  
tears, 92, 93*f*, 1347, 1347*f*, 1354  
transplantation in dry age-related macular degeneration, 2258  
visual acuity after, 2261*f*

Retinal pigment epithelium (RPE) cells, 767–772  
    cell-based delivery of trophic factors, 768

differentiation of hESCs and hiPSCs into, [768–769](#)  
in PVR, [1868](#)

Retinal pigment epithelium (RPE) transplantation  
on aged Bruch's membrane  
    resurfacing of, [2320–2321](#)  
    survival and differentiation of, [2320](#)  
in age-related macular degeneration, [2310](#)  
autologous, [2318](#)  
cell selection for, [2310–2312](#)  
graft failure in, [2318–2319](#), [2319f](#)  
immune response to, [2317–2318](#)  
rejection of, [2318](#)  
replacement, [2319–2321](#)  
results of, in humans, [2313–2314](#), [2315f](#)  
on scaffold supports, [2313](#)  
stem cell-derived, [2310–2312](#), [2310t](#)

Retinal pigment epithelium (RPE)-rod complex, diagrammatic  
representation of, [899f](#)

Retinal pigment epithelium-choroid graft surgery, for age-related  
macular degeneration, [2258](#), [2262–2263](#), [2262f–2263f](#)

Retinal pit, [566f](#)

Retinal progenitor cells, [765](#)  
    tracing of, methods for, [378–379](#)

Retinal prosthesis  
    architecture, [794–797](#), [797f](#)  
    for artificial vision, [2342–2351](#), [2353f](#)  
        Argus I system in, [2343](#), [2354f](#)  
        Argus II system in, [2343–2344](#), [2344f](#)

- epiretinal prosthesis in, [2343–2345](#)
- retinitis pigmentosa in, [2342–2343](#)
- subretinal prosthesis in, [2346–2349](#), [2346f–2347f](#)
- suprachoroidal and transscleral retinal prostheses in, [2349–2351](#), [2350f–2352f](#)

Retinal reattachment, [698–701](#), [700f](#)

- perfluorocarbon liquid for, [2052–2053](#), [2053f](#)

Retinal redundancy, [1959](#)

Retinal sheen dystrophy, [552](#)

Retinal shortening

- due to proliferative vitreoretinopathy (PVR), [2061](#)
- surgical technique for, [2061](#)

Retinal slippage, retinectomy and, [2067](#)

Retinal stem, [765–767](#)

Retinal structures, visualization of, [181–182](#), [181f](#)

Retinal surface, traction on, scleral buckles and, [1884–1885](#), [1884f–1886f](#)

Retinal surgery, clinical trials for, [1818–1820](#)

Retinal tears, [1763](#), [2085–2087](#), [2087f](#)

- in posterior vitreous detachment, [562](#)
- in retinal lattice, [561f](#)

Retinal telangiectasis, [28f](#)

Retinal texture analysis, [213f](#), [215](#)

Retinal thickening

- distribution of, [1070–1071](#)
- magnitude of, [1071](#)
- visual acuity and, [1072–1073](#), [1075f](#)

Retinal thickness, [79](#), [80f](#)

Retinal tissue, retinotomy and, [2057](#)

Retinal toxicity, patterns of, [1719b](#)

Retinal toxoplasmosis, in HIV infection, [1643](#), [1644f](#)

Retinal transduction, characteristics of different vectors, [751–752](#)

Retinal vascular (arteriolar) occlusive diseases, in blocked retinal fluorescence, [14](#)

Retinal vascular conditions, wide-field imaging for, [148](#), [150f](#)

Retinal vascular diseases, pediatric, [1246–1267](#)  
newborn screening for, [1263](#)

Retinal vascular filling defect, in blocked choroidal fluorescence, [17](#), [20f–21f](#)

Retinal vascular hyperpermeability, [1062](#)

Retinal vascular map, [182](#)

Retinal vascular parenchyma, [182](#)

Retinal vascular proliferation  
clinical features of, [2430–2431](#), [2431f](#)  
treatment of, [2434](#)

Retinal vasculature, [181f](#)  
oxidative injury to, [585–586](#)  
SCD and, [1206](#), [1208f](#)

Retinal vasculatures, *versus* choroidal vasculatures, [488–489](#), [489f](#)

Retinal vasculitis, [1682](#)  
in ARN syndrome, [1712](#), [1712f](#)  
epidemiologic spectrum of, [1667–1668](#)  
primary, [1666](#)

Retinal vasculogenesis, normal, [1249](#), [1249f–1250f](#)

Retinal vasoconstriction, primary stage of, [1247](#)

Retinal vein, central, [1666](#)

Retinal vein occlusion (RVO), [100](#), [101f](#), [638–640](#), [2204–2205](#)  
central or branch, serous retinal detachment in, [707–708](#)  
ILM peeling, [2204–2205](#)  
in pregnancy, [1774](#)  
retinal hypoxia and, [496–497](#)  
vitrectomy in, role of, [2204](#)  
wide-field imaging for, [148](#), [149f–150f](#)

#### Retinal vessels

detection of, [206](#), [206f–207f](#)  
from three-dimensional OCT, [215–216](#), [216f](#)  
traction on, [565f](#)

Retina-related clinical trials, [1796–1820](#)

#### Retinectomies, [2052–2071](#)

for anterior retinal displacement, [2063–2065](#), [2065f–2067f](#)  
complications of, [2068–2069](#)  
extensive periretinal fibrous proliferation and, [2063](#)  
for giant retinal tear contraction and fibrosis, [2065](#), [2067f](#)  
for glaucoma treatment, [2057](#)  
management of, [2065–2067](#)  
, proliferative vascular retinopathy and, [2065](#)  
for prophylactic removal of anterior flap of horseshoe tears, [2063–2065](#)  
relaxing retinotomy and, [2057–2061](#)  
results of, [2068](#)  
retinal contraction and  
circumferential, [2061–2063](#), [2064f](#)  
focal or diffuse, [2061–2063](#), [2063f](#)

- intrinsic, [2063](#)
- for retinal incarceration, [2059–2061](#), [2061f](#)
  - surgical technique for, [2060–2061](#), [2060f](#), [2062f](#)
- for retinoschisis, congenital, [2065](#)

Retinectomy, [1929–1930](#), [1930f](#)

Retinitis

- in ARN syndrome, [1709](#), [1710f](#)
- cytomegalovirus
  - pathogenesis, diagnosis, and clinical manifestations of, [1628–1630](#), [1628f](#), [1630f](#)
  - wide-field imaging for, [148–149](#), [153f–154f](#)
- infectious, [893](#)

Retinitis pigmentosa (RP), [440–441](#), [585](#), [614](#), [973f](#), [975](#), [1779](#), [2321](#)

- abnormal intracellular trafficking, [906](#)
- adaptive optics scanning laser ophthalmoscopy, [881](#)
- adult-onset Refsum disease, [891](#)
- age of onset, [883](#)
- and allied disorders, [861–935](#)
- anterior segment abnormalities, [870](#)
- antioxidants and, [820](#)
- apoptosis, [916–917](#)
- autofluorescence, [881](#), [882f](#)
- autoimmune paraneoplastic retinopathy, [894](#)
- autosomal dominant, [862f](#)
- Bardet-Biedl syndrome, [890–891](#), [906](#)
- “BBSome”, [906](#)
- cataract extraction, [911](#)

Subretinal cell transplants, non-RPE, [2312](#)

Subretinal cysticercus, [1696f](#)

Subretinal drusenoid deposits (SDD), [87](#), [88f](#), [1315–1317](#)

- Bruch's membrane lesion and, [532f](#), [534–535](#)
- clinical appearance of, [1315](#), [1316f](#)
- histology of, [1316](#), [1317f](#)
- imaging of, [1316–1317](#)

Subretinal fibrosis

- diabetic macular edema and, [1072](#)
- punctate inner choroidopathy and, [1536](#), [1536f](#)

Subretinal fluid, [89](#), [131f](#)

- circumscribed choroidal hemangioma, [2638](#)
- transport, retinal adhesion and, [512–513](#), [514f](#)

Subretinal fluid drainage, [1904–1907](#)  
after, [1905–1906](#), [1906f](#)  
air injection, [1906](#), [1906f](#)  
cut down techniques in, [1905](#), [1905f](#), [1905.e1f](#)  
encirclement, [1906–1907](#), [1907f–1908f](#)  
indications for, [1904](#)  
single-stage techniques in, [1905](#), [1905f](#), [1905.e1f](#)  
sites, location of, [1904](#)  
technique of, [1904–1905](#)  
timing in, [1904](#)

Subretinal gas, [1967](#)

Subretinal hemorrhage, [57f](#), [2234](#), [2509](#)  
causing hypofluorescent blockage, [17f](#)  
etiology of, [2234](#)  
management options of, [2235–2237](#)  
    surgical removal of blood, [2235](#)  
    vitrectomy, [2235](#)  
natural history of, [2234–2235](#)

Subretinal implants, [794–797](#)

Subretinal injection, [749–750](#)  
with protection to fovea, [751f](#)  
in retinal gene therapy, [751](#)

Subretinal large nematode, [1692f](#)

Subretinal mass, retinotomy and, [2057](#)

Subretinal material, in blocked choroidal fluorescence, [15–16](#), [17f–19f](#)

Subretinal neovascularization, [31f–32f](#)

Subretinal perfluorocarbon  
  liquid, [1974](#)  
  proliferative diabetic retinopathy and, [2123](#)

Subretinal proliferation, management of, [1925](#), [1926f](#)

Subretinal prosthesis, for artificial vision, [2346–2349](#), [2346f–2347f](#)

Subretinal protein, retinal adhesion and, [512–513](#), [514f](#)

Subretinal space, [2592](#)  
  retinal adhesion and  
    effects of vitreous in, [516](#)  
    mechanical forces inside, [508–513](#)  
    mechanical forces outside, [506](#)

Subretinal transplants, of Schwann cells rescue photoreceptors, [2322](#), [2323f](#)

Sub-Tenon anesthesia, in scleral buckling surgery, [1891](#)

Sub-Tenon carboplatin, [2394](#)

Sulfa antibiotics, retinal folds from, [1734](#)

Sulfonylureas, for diabetes mellitus, [1058](#)

Sulforaphane, [590](#)

Sulfur redox couples, [582](#)

Sulphonamide, retinal folds from, [1734](#)

Sulphur hexafluoride (SF<sub>6</sub>), as intraocular gas, [1958](#), [1964](#)

Sungazing injuries, [1750](#)

Sunlight exposure  
  AMD and, [1277](#)  
  uveal melanoma and, [2518](#)

Superoxide dismutase (SOD) 2, [817](#)

Superoxide radicals, [817](#)

Superparamagnetic iron oxide (SPIO) nanoparticles, [791](#)

Supplemental antioxidants, in oxidative stress, [589–590](#)

Supplemental Therapeutic Oxygen for Prethreshold Retinopathy of Prematurity (STOP-ROP), [1815](#)

Suprachiasmatic nucleus (SCN), [438](#)

Suprachoroidal and transscleral retinal prostheses, [2349–2351](#), [2350f–2352f](#)

Suprachoroidal hemorrhage (SCH)

- during cataract surgery, [2371](#)
- massive, [2371](#)
- perfluorocarbon liquid (PFCL) and, [1973](#), [1974f](#)

“Suprachoroidal transretinal stimulation”, [2349](#), [2350f](#)

Surface tension, silicone oil (SO) and, [1977–1978](#)

Surgery

- for Coats disease, [1197–1198](#), [1199f](#)
- for ocular trauma, [2081–2106](#)
- pharmacology at, [2358–2367](#)
  - antiproliferative agents in, for proliferative vitreoretinopathy, [2360](#)
  - for endophthalmitis, [2364–2365](#)
  - tissue plasminogen activator in vitreoretinal surgery, [2360–2361](#)
  - VEGF inhibitors in vitreoretinal surgery, [2362–2364](#)
  - vitreolysis, [2358–2360](#)
  - vitreoretinal interface, visualization of, [2361–2362](#), [2361t](#)

Surgical technology, nanomedicine and, [800–802](#), [802f](#)

Surveillance, Epidemiology, and End Results (SEER) program, [2515](#)

Susac syndrome, in pregnancy, [1774](#)

Suspicious nevi, [2511](#)

SUSTAIN study, for ranibizumab, [1384](#), [1385f](#)

Sustained delivery, [831–832](#)

Sustained drug delivery, for age-related macular degeneration, [1403–1406](#)

- adeno-associated viral vector (AAV) gene transduction as, [1404–1405](#)
- complement inhibition as, [1405–1406](#)
- encapsulated cell technology as, [1403](#), [1403f](#)
- hI-con1 as, [1405](#)
- port delivery system as, [1403–1404](#)
- regorafenib as, [1405](#)
- Replenish MicroPump as, [1404](#), [1404f](#)

Suture needle drain, [1905.e1f](#)

Sutureless vitrectomy, [2013–2014](#)

Sutures, scleral, [1899–1903](#), [1901f–1903f](#)

- tying, [1902–1903](#), [1904f](#)

Swedish interactive threshold algorithm (SITA), [352](#)

Swept source OCT (SS-OCT), [77–78](#), [2242](#)

- choroidal nevi and, [2510](#)

Swept source optical coherence tomography, of angioid streaks, [1440–1441](#)

Sympathetic ophthalmia, [1496–1504](#), [2102](#)

- clinical findings of, [1499](#), [1499f](#)
- course and complications in, [1501](#)
- diagnosis of, [1499](#), [1500f–1501f](#)
- epidemiology of, [1496](#)
- immunopathology of, [1497–1498](#), [1497f–1498f](#)

nonrhegmatogenous retinal detachment in, [1836–1837](#)  
pathogenesis of, [1496–1497](#)  
prevention of, [1502](#)  
prognosis of, [1502](#)  
therapy for, [1501–1502](#)

Symptomatic circumscribed choroidal hemangiomas treated with photodynamic therapy (PDT), [2646t](#)

Symptomatic posterior vitreous detachment (PVD), [562](#)

Synchronous nonocular cancers, PET/CT and, [2609](#)

Synchysis scintillans, [277](#)

Syneresis, vitreous, [277](#)

Synthetic scaffolds, [799](#), [799f–800f](#)

Syphilis

- in bacterial retinitis, [1645–1646](#)
- ocular, wide-field imaging for, [151f](#)
- pseudoretinitis pigmentosa differential diagnosis, [893](#)
- recommended treatment of, [1675t](#)

Syphilitic uveitis, [1674–1675](#)

- associated with Lyme disease, [1675–1677](#)
- course and outcome of, [1675](#)
- diagnosis of, [1673–1674](#), [1674f](#)
- differential diagnosis of, [1674](#), [1674t](#)
- epidemiology of, [1672–1673](#)
- ocular manifestations of, [1673](#), [1673f](#)
- pathogenesis of, [1672–1673](#)
- treatment of, [1674–1675](#)

Systemic anticoagulation, for branch retinal vein occlusion, [1159](#)

Systemic arterial hypertension, ocular ischemic syndrome and, [1235](#)

Systemic chemotherapy, in leukemia, [2666](#)

Systemic CMV infection, screening techniques for, [1630–1631](#)

Systemic disease, antibiotic therapy for, [1678](#)

Systemic ganciclovir, active cytomegalovirus retinitis with, [1640f](#)

Systemic immune response, antigen-specific “deviant,” induction of, [2317](#)

, Systemic intravenous chemotherapy, for retinoblastoma, [2393–2394](#)

Systemic lupus erythematosus, [1605–1609](#)

- American College of Rheumatology criteria for, [1605b](#)
- articular and systemic disease of, [1605–1606](#)
- epidemiology of, [1605](#)
- ocular disease of, [1606–1608](#), [1606f–1608f](#)
- treatment of, [1608–1609](#)
  - of ocular disease, [1609](#)
  - of systemic disease, [1608–1609](#)

Systemic lupus erythematosus (SLE), [1666](#)

Systemic medical conditions, treatment of, [1174](#)

Systemic medications, proliferative diabetic retinopathy and, [1103–1104](#)

Systemic metastasis

- management of, [2557–2558](#)
- treatment of, [2610–2611](#)

Systemic sclerosis, [1610–1611](#)

- articular and systemic disease of, [1610](#)
- epidemiology of, [1610–1611](#)
- ocular disease of, [1610](#)

treatment of, [1610–1611](#)

of ocular disease, [1611](#)

of systemic disease, [1610–1611](#)

Systemic vascular diseases, CRVO and, [1169b](#)

Systemic vasculitis, APMPPE and, [1524](#)

## T

Tablets applications, for color vision screening, [337](#)

Tadalafil, uveitis from, [1739](#)

Takayasu's arteritis

The American College of Rheumatology Criteria for the Classification of, [1615b](#)

articular and systemic disease of, [1615](#)

epidemiology of, [1615](#)

ocular disease of, [1615](#)

treatment of, [1615](#)

Talc, retinopathy from, [1728–1729](#), [1728f](#)

Tamoxifen, crystalline retinopathy from, [1734](#), [1736f–1737f](#)

Tamponade

gas, in pediatric vitreoretinal surgery, [2176](#)

internal, giant retinal tear surgery, [2077](#)

proliferative diabetic retinopathy and, [2120–2121](#)

Tangent screen field, [349](#), [350f](#)

Tantalum rings, [2583f](#)

Tapetal-like reflex, [866–867](#)

Targeted laser photocoagulation (TRP)

in uveitis, [148–149](#)

UWF imaging and, [147–148](#)

Targeted mutations, [227–228](#)

Targeting, [834](#)

- ligands, molecular imaging and, [192](#)

T-cell origin, [2660–2661](#)

T-cell traffic, [628](#)

Tear, of the RPE, [92](#), [93f](#)

Telangiectasis, [29f](#)

Telemedicine, ROP and, [1268](#), [1269f](#)

- accuracy of, [1268–1270](#), [1269t–1270t](#)
- barriers and challenges in, [1271](#)
- cost-effectiveness of, [1270](#)
- evaluation of, [1270–1271](#)
- future directions of, [1271](#)
- image quality of, [1270](#)
- satisfaction of, [1270](#)
- speed of, [1270](#)

Tele-perimetry, [348](#)

Telescreening, for diabetic retinopathy, [1129–1135](#)

- automated retinal image analysis for, [1134](#)
- compression in, [1131](#)
- cost-effectiveness of, [1133](#)
- data transfer, archiving, and retrieval in, [1131](#)
- efficacy of, [1133](#)
- guidelines from American Telemedicine Association, [1130](#)
- image acquisition in, [1131](#)
- macular edema and, [1132](#)
- ophthalmologist-led and ophthalmologist-based models for,

differences between, [1129t](#)  
patient satisfaction of, [1133](#)  
program evaluation for, [1133](#)  
quality assurance of, [1133](#)  
reading center for, role of, [1132–1133](#)  
security and documentation in, [1131–1132](#)  
smartphones for, [1134](#)  
steps of, [1130–1131](#), [1130f](#)

Teletherapy, for retinoblastoma, [2399–2400](#), [2399f–2400f](#)

Telodendria, [415–416](#)

Temperature, retinal adhesion and, [505–506](#), [505f](#)

Tenofovir, [1624](#)

Tenon's capsule, [1889–1890](#), [1889f](#)

Tenth-value layer (TVL), [2567](#)

Teratoid medulloepitheliomas, medulloepithelioma and, [2653](#)

Teratoneuroma, [2651](#)

Terson syndrome, [280](#), [287f](#), [1765–1766](#), [1765f](#)  
pediatric vitreoretinal surgery for, [2178–2179](#), [2179f](#)

Terson's sign, [280](#)

Tetracyclines, for diabetic retinopathy, [1040–1041](#)

TFSOM UHHD (“To Find Small Ocular Melanomas Using Helpful Hints Daily”) mnemonic, [2503](#)

TGF- $\beta$ , [Transforming growth factor- \$\beta\$](#)

TH17-mediated, immune responses in AMD, [632](#)

The Macular Telangiectasia (MacTel) Project, [1181](#)

Theranostics, [792](#), [793f](#)

Therapeutic vitrectomy, [1594](#)

Therapeutics, nanomedicine and, [792](#), [793f](#)

Thermal chorioretinal adhesions, [1883–1884](#)

Thermal choroidotomy, [1905](#), [1905f](#)

Thermal laser, circumscribed choroidal hemangioma, [2644](#)

Thermal laser photocoagulation

- for extrapapillary retinal hemangioblastomas, [2432–2433](#)
- for polypoidal choroidal vasculopathy, [1462–1463](#)

Thermoluminescent ring dosimetry measurements, [2573](#)

Thiazolidinediones

- for diabetes mellitus, [1056](#)
- for proliferative diabetic retinopathy and, [1104](#)

Thioridazine, [364](#)

- retinal toxicity from, [1003](#), [1003f](#), [1723–1724](#), [1723f](#)
- for retinitis pigmentosa, [894](#)

Three-dimensional (3D) reconstructions, [276](#), [276f–277f](#)

Three-dimensional datasets, OCT and, [78](#), [78f](#)

Three-dimensional scaffold, [798–799](#)

Thrombin, [1858](#)

- for DIC, [1241](#)

Thrombocytopenia, in leukemia, manifestations of, [2664–2665](#)

Thrombolytics, for central retinal artery occlusion, [1142](#)

Thrombopoietin-receptor agonists (TPO-RAs), for ITP, [1241](#)

Thrombotic thrombocytopenic purpura (TTP), [1241](#)

- in pregnancy, [1774](#)

<sup>3</sup>H-thymidine “birthdating” technique, [378](#)

*Thyroid hormone receptor-β2*, [383](#)

Tie2, [646–647](#)

Tight junctions, endothelial junctions and, [668–669](#)

Time domain OCT (TD-OCT), [77–78](#)

Timolol maleate, [836](#)

*TIMP3* gene, [983](#)

Tissue

- change, balance of, in early AMD, [1289](#), [1289f](#)
- lasers beam delivery to, [846–848](#)
- light, interactions with, [848–857](#)

Tissue factor, [1379](#)

Tissue inhibitor of metalloproteinase 3 (*TIMP3*), [1279](#)

Tissue inhibitors of metalloproteinases, [1378–1379](#)

- TIMP-3*, and age-related macular degeneration, [1374–1375](#)

Tissue plasminogen activator

- optical coherence tomography and, [172](#)
- plus subretinal air/subretinal anti-VEGF, [2236](#)
- with pneumatic displacement
  - intravitreal, [2235–2236](#)
  - subretinal injection of, [2235–2236](#)
- in vitreoretinal surgery, [2360–2361](#)

Tissue resident macrophages, [626–628](#), [627f](#), [627t](#)

TNF- $\alpha$ , [670](#)

Toll-like receptors (TLR), [628](#)

Tool ergonomics, [1920–1921](#)

Topical delivery, [836](#)

- nanocomposites for, [839–840](#)

Topical epinephrine, cystoid macular edema from, [1732](#)

Topiramate, retinal folds from, [1734](#), [1736f](#)

Toxemia of pregnancy, Hemolysis, elevated liver enzymes, and low platelets (HELLP) syndrome

Toxic maculopathy, 362

Toxic neuritis, in fluorescein injection, 3

Toxic retinopathies, visual field and, 362–364, 364f–365f

Toxic tumor syndrome, 2574, 2599f

Toxicity, 47

in choroidal metastases, 2625

*Toxocara canis*, life cycle of, 1687f

Toxocariasis, ocular, 1685–1690

atypical presentations, 1688

chronic endophthalmitis, 1688

clinical presentations of, 1686–1688

Coats disease, 1690

diagnosis of, 1688–1689

differential diagnosis of, 1689–1690

, familial exudative vitreoretinopathy, 1690

forms of endophthalmitis and uveitis, 1690

parasitology of, 1686

pathophysiology of, 1686

peripheral granuloma, 1686–1687

persistent hyperplastic primary vitreous, 1690

posterior pole granuloma, 1687–1688, 1688f–1689f

retinoblastoma, 1689

retinopathy of prematurity, 1690

toxoplasmosis, 1690

treatment of, 1690

*Toxoplasma gondii*, [1681](#)

*Toxoplasma* infection, case in retinal biopsy, [2303b](#), [2304f](#)

Toxoplasmic chorioretinitis, in vitreous biopsy, [2300](#)

Toxoplasmic retinochoroiditis, [1682](#), [1779](#), [2468](#), [2469f](#)  
atypical, [1682](#)

Toxoplasmosis, [364–365](#), [1690](#)  
eye, [1681](#)  
ocular syphilis *vs.*, [1674t](#)

Traction retinal detachment, proliferative diabetic retinopathy and, [2109](#), [2110f](#)

Traction retinoschisis, [565f](#)

Tractional detachment, evidence-based trials and, [2126](#), [2126t](#)

Tractional macular edema, [Vitreoretinal traction](#)

Tractional retinal detachment, [1823](#)

Traditional fundus camera, montage with, [143–144](#), [144f](#)

Traditional routes of administration, drug delivery and, [836](#)

Traditional time-domain, circumscribed choroidal hemangioma, [2642](#)

Transconjunctival, small-gauge vitrectomy, [1921](#), [1921f](#)

Transcription, DNA-RNA, [713–714](#)

Transducin's GTPase activity, [394](#)

Transforming growth factor- $\beta$ , [460t](#), [671](#), [672f](#)  
in patients with PVR, [1869](#)  
proliferative vitreoretinopathy and, [1858–1859](#)

Transient receptor melastatin 1 (TRPM1) channel, [423–424](#)

Translation, protein, [714](#)

Transmitted fluorescence, [19](#), [24–41](#)  
abnormal choroidal vessels in, [30–31](#), [31f–33f](#)

abnormal retinal and disc vessels in, [25–30](#), [27f–30f](#)  
characteristics of, [24](#)  
leakage in, [31–32](#)  
    choroidal, [34–41](#), [38f–43f](#)  
    disc, [34](#), [34f](#)  
    retinal, [34](#), [35f–37f](#)  
    vitreous, [32–34](#)  
optic disc edema in, [34](#)  
papilledema in, [34](#)  
Transorbital sonography, [302](#)  
Transplantation  
    of autologous graft of RPE, [2255](#)  
    of full-thickness patch from midperiphery, [2255–2256](#)  
Transplantation frontiers, [2309–2339](#)  
    photoreceptor transplantation in, [2321](#)  
    RPE transplantation in, [2310](#), [2321](#)  
Transpupillary thermotherapy (TTT), [1478](#), [2524](#), [2551–2552](#), [2552f](#),  
[2556](#), [2576](#)  
    as ancillary treatment of choroidal melanoma, [2602–2604](#), [2603f–](#)  
    [2604f](#)  
    for angioid streaks, [1441–1442](#)  
    circumscribed choroidal hemangioma, [2644–2645](#)  
    as primary treatment of choroidal melanoma, [2602](#), [2602f](#)  
    technique, [2602](#)  
Transscleral cryotherapy, for extrapapillary retinal  
    hemangioblastomas, [2433](#)  
Transscleral diode cyclophotocoagulation, circumscribed choroidal  
    hemangioma, [2645](#)

## Trauma

ocular, 1865–1874, 2081–2106

anatomic changes in, 1865–1866, 1866*f*

classification of, 1865*b*

experimental models for, 1867

histopathologic findings of, 1866–1867, 1866*f*

therapeutic aspects of, 1870–1871

wound healing and traumatic proliferative vitreoretinopathy  
and, 1867–1870, 1868*f*

orbital, macular hole and, 2218–2219, 2218.e2*f*

retinopathy, Retinitis pigmentosa, traumatic retinopathy

silicone oil (SO) and, 1980

vitreoretinal effects of, 569

blunt, 569, 570*f*

posterior penetrating, 569, 571*f*

Traumatic chorioretinopathies, 1757–1770

direct ocular injury, 1757–1764

choroidal rupture, 1758–1760, 1759*f*

commotio retinae, 1757–1758, 1757*f*

optic nerve avulsion, 1764, 1764*f*

sclopetaria (traumatic chorioretinal rupture), 1760–1761, 1760*f*

traumatic macular hole, 1761–1762

traumatic retinal detachment, 1762–1764, 1762*f*

indirect ocular injury, 1764–1767

Purtscher retinopathy, 1764–1765, 1765*f*

shaken baby syndrome, 1766–1767, 1767*f*

Terson syndrome, 1765–1766, 1765*f*

Valsalva retinopathy, [1766](#), [1766f](#)

Traumatic endophthalmitis, in open-globe injury, [1870](#)

Traumatic incarceration, of retina, [1972](#)

Traumatic macular hole, [1761–1762](#), [1761f](#)  
pediatric vitreoretinal surgery for, [2177–2178](#), [2178f](#)

Traumatic retinal detachment, [1762–1764](#), [1762f](#)

Treatment, in charged-particle irradiation of uveal melanoma, [2583–2585](#)  
clinical findings in treated patients, [2585](#)  
follow-up, [2584–2585](#)  
operative technique, [2583](#), [2583f–2584f](#)  
patient selection, [2583](#)  
planning, [2583](#)  
radiation dose, [2584](#)  
techniques, [2583–2584](#), [2584f](#)

Treatment of age-related macular degeneration with photodynamic therapy (TAP), [1806–1807](#)

Treg cells, [658](#)

Tregs, [629](#)

Triamcinolone  
for branch retinal vein occlusion, [1162](#)  
for macular edema, [678](#)  
for radiation retinopathy, [1224](#)  
in vitreous base shaving, [1970](#)

Triamcinolone acetonide

Vision  
    decreased, in ARN syndrome, [1709](#)  
    factors affecting salvage of, in retinoblastoma, [2387–2388](#)  
    vitamin A and, [459](#)

Vision loss, central, retinitis pigmentosa and, [865](#), [865f](#)

Vision-related quality of life (QOL), in bilateral severe AMD, following MTS360, [2244](#)

VISTA and VIVID studies, treatment trials of, [1802](#)

Vistech VCTS 6500, [344f–345f](#)

Visual acuity, [340–347](#), [2585–2586](#), [2595–2596](#), [2596f](#)

of age-related macular degeneration, after surgery, [2261f](#)

in Best macular dystrophy, [957](#)

in central retinal artery occlusion, [1136](#)

CHRRPE and, [2495–2496](#)

of MST360, for age-related macular degeneration, [2245](#), [2246t](#)

in ocular ischemic syndrome, [1228](#)

ranibizumab and, [1382–1384](#), [1383f](#)

retinal thickening and, [1072–1073](#)

in Stargardt disease, [965](#)

Visual acuity tests, [340–343](#)

administration, [342](#)

chart design, [340–341](#)

contrast, [341–342](#)

contrast sensitivity, [Contrast sensitivity tests](#)

electronic acuity tests, [343](#)

layout, [340–341](#)

luminance, [341–342](#)

near acuity tests, [342–343](#)

optotypes, [340](#)

reading acuity tests, [342–343](#)

scoring, [342](#)

specifying letter size, [342](#)

test distance, [341](#)

words *versus* continuous text, [342–343](#)

Visual cortical evoked potentials (VEP), neuroprotection and, [812–](#)

Visual cycle, [457](#), [457f](#)

Visual cycle inhibitors, for age-related macular degeneration, [1410](#)

Visual defects

in optic disc drusen, [1787–1788](#)

in optic disc pits, [1790](#)

Visual evoked potential (VEP), [269–271](#), [270f](#)

focal macular, [270f](#), [271](#)

of ocular ischemic syndrome, [1235](#)

Visual field, variables affecting, [353b](#)

Visual field defect

due to drainage retinotomy, [2056](#)

macular hole and, [2225–2227](#)

Visual field loss, due to retinectomy, [2069](#)

Visual field tests, [348](#)

age-related macular degeneration, [358–360](#)

color perimetry, [367](#)

diabetic retinopathy, [353–358](#), [357f](#)

epiretinal membrane, [361–362](#)

infectious retinopathies, [364–366](#)

inflammatory retinopathies, [364–366](#)

island of Traquair, [348](#), [350f](#)

layer-by-layer perimetry, [367](#)

macular holes, [361–362](#), [362f](#)

after pars plana vitrectomy, [363f](#)

methods of, [348–353](#)

microperimetry, [352](#)

- nondiabetic macular edema, 358
- qualitative techniques, 349–350
- quantitative techniques, 350–352
- reliability of, 352–353
- reproducibility of, 352–353
- retinal detachment, 366
- retinitis pigmentosa, 353, 354*f*
- tele-perimetry, 348
- toxic retinopathies, 362–364, 364*f*–365*f*
- tumors, 366–367

#### Visual fields

- loss of, retinitis pigmentosa and, 862–865, 862*f*
- for simplex retinitis pigmentosa, 874*f*

#### Visual function

- in Best macular dystrophy, 957
- impact of NNVAMD on, 1332–1333
- macular telangiectasia and, 1183–1185
- in Stargardt disease, 969–973, 973*f*–974*f*

Visual impairment, from NNVAMD, 1337–1339, 1338*f*

#### Visual loss, 2498

- in cavernous hemangioma, 2423
- in ocular ischemic syndrome, 1227–1228, 1228*f*
- unexplained, silicone oil (SO) and, 1988

#### Visual prostheses, for artificial vision, 2341–2351

- cortical prosthesis in, 2341–2342
- epiretinal prosthesis in, 2343–2345
- optic nerve prosthesis in, 2342

retinal prosthesis in, [2342–2351](#)  
subretinal prosthesis in, [2346–2349](#), [2346f–2347f](#)

Visual system, plasticity of, [756–757](#)

Visualization, reduced, proliferative diabetic retinopathy and, [2122](#)

Visudyne™, [848](#)

Vital dyes, macular hole and, [2222–2223](#)  
brilliant blue, [2222](#)  
indocyanine green and infracyanine, [2222](#)  
trypan blue, [2222](#)

Vitamin A, vision and, [459](#)

Vitamin A supplements, [912–913](#)

Vitamin C, for AMD, [1276](#)

Vitamin E, for AMD, [1276](#)

Vitamin E, in ROP, [1258](#)

Vitamins, for age-related macular degeneration, [1408–1410](#)

Vitelliform lesions, with non-neovascular AMD, [1317–1318](#), [1318f](#)

Vitrasert ganciclovir implant, [837](#), [837f](#)

Vitreotomy, [2009](#), [2116–2120](#), [2116f](#), [2235](#)  
conventional indications for, [2012](#), [2012f](#), [2012t](#)  
CRVO and, [1175](#)  
for diabetic macular edema, [1082](#)  
diagnostic, for uveitis, [2287–2291](#)  
biopsy, retinal/choroidal, [2289](#)  
cytokine measurement, [2291](#)  
cytologic evaluation, [2290](#)  
flow cytometry, [2291](#)  
histopathologic evaluation, [2290](#)

indications for, [2288b](#)  
microbiologic culture, [2290](#), [2290f](#)  
molecular analysis, [2290–2291](#)  
surgical principles and techniques, [2287–2289](#)  
vitrectomy specimens, diagnostic techniques for, [2289–2291](#)  
vitreous samples, handling and preparation of, [2288f](#), [2289](#)  
examination before, [323f](#), [323t](#)  
extensive, for macular hole, [2221](#)  
giant retinal tear, [2075–2076](#)  
for macular edema, [681](#)  
macular hole and, [85](#), [2219–2220](#), [2219f](#)  
pneumatic retinopexy and, [1952–1953](#)  
in postoperative macular edema, [2205](#)  
in primary vitreoretinal lymphoma (PVRL), [2677](#)  
for proliferative diabetic retinopathy (PDR), [1116](#), [1116b](#)  
retinal macroaneurysms and, [1153](#)  
SCD and, [1212](#)  
with sheathotomy  
    for macular edema, [1163](#)  
    for underlying etiology, of branch retinal vein occlusion, [1159–1160](#)  
small-gauge, [1921](#), [1921f](#)  
for stage 5 ROP, [2163](#), [2163f–2165f](#)  
supplementary buckle and, [2012–2013](#)  
sutureless, [2013–2014](#)  
therapeutic, for uveitis, [2291–2293](#)  
    indications, [2291](#)

- outcomes, [2292–2293](#), [2293f](#)
- surgical principles and techniques, [2292](#)
- for tractional macular edema, [2202–2203](#)
- in “U” (horseshoe) tears, [2012–2014](#)
- in uveitic macular edema, [2205](#)
- 27G vitrectomy, problem during, [2373](#)
- Vitrectomy cutter, [2113](#), [2113f](#)
- Vitreitis, in ARN syndrome, [1710f](#)
- Vitreolysis
  - for macular hole, [2227](#)
  - pharmacologic, [2206](#)
- Vitreomacular adhesion (VMA) syndrome, [83–84](#), [84f](#)
- Vitreomacular interface, [552](#), [555f](#)
  - aging of, [555–557](#), [558f](#)
- Vitreomacular traction, [2602](#)
  - macular hole and, [2214](#)
  - in retinitis pigmentosa, [2206](#)
- Vitreomacular traction (VMT) syndrome, [83](#), [84f](#)
  - in anomalous posterior vitreous detachment, [565](#), [566f](#)
  - optical coherence tomography imaging for, [167–175](#)
- Vitreon, [Perfluorophenanthrene](#)
- Vitreopapillary interface, [552–553](#), [556f](#)
- Vitreoretinal adhesion, [551](#), [554f](#)
- Vitreoretinal degenerations, hereditary, [936–952](#)
  - features of, [937t](#)
- , Vitreoretinal disorders, pediatric, surgery for, [2170–2193](#)
  - general aspects of, [2170–2173](#)

- hereditary vitreoretinopathies in, [2182–2190](#)
- injuries in, [2176–2190](#)
  - closed globe, [2176–2178](#)
  - direct, [2176–2178](#)
  - indirect, [2178–2180](#)
  - open globe, [2176](#), [2177f](#)
- pediatric retina, diseases of, [2181–2182](#)
- surgical considerations and techniques in, [2173–2176](#)
- Vitreoretinal interface, [545–553](#)
  - alterations of, [1063](#)
  - inner limiting membrane in, [547–551](#), [552f–553f](#)
  - intervening extracellular matrix of, [551](#)
  - posterior vitreous cortex in, [545–547](#), [550f](#)
  - SCD and, [1206](#)
  - topographic variations of, [551–553](#)
  - visualization of, [2361–2362](#)
    - agents for, [2361](#), [2361t](#)
    - epimacular membranes, current dyes for, [2362f](#)
    - internal limiting membrane, current dyes for, [2361](#), [2362f](#)
    - perspectives of, [2361–2362](#)
- Vitreoretinal interface disorders, [83–86](#)
  - epiretinal membrane, [85–86](#), [85f](#)
  - macular hole, [84–85](#), [85f](#)
  - membrane peeling in, [171–172](#), [172f](#)
  - vitreomacular adhesion (VMA) syndrome, [83–84](#), [84f](#)
- Vitreoretinal junction, enzymatic manipulation of, [2165](#)
- Vitreoretinal surgery

air-gas exchange, [1928](#), [1928f](#)  
air-silicone exchange, [1929](#), [1930f](#)  
anatomy of, [1916–1917](#)  
complications in, [2368–2374](#)  
    27G vitrectomy, problem during, [2373](#)  
    Argus II array implantation, [2373–2374](#)  
    brilliant blue, subretinal injection of, [2370](#)  
    haptics, subluxated intraocular lens without, [2368–2369](#)  
    in high myopia, induction of PVD, [2369](#)  
    hypotony maculopathy, surgical management of, [2370](#)  
    intraoperative choroidal detachment, [2370–2371](#)  
    large glass intraocular foreign body, removal of, [2374](#)  
    peeling, internal limiting membrane (ILM), [2369–2370](#)  
    during peeling, iatrogenic retinal breaks, [2369](#)  
    perfluorocarbon-induced macular hole, [2372](#)  
    PVR, subretinal membrane and, [2372–2373](#)  
    in retinal detachment, induction of PVD, [2369](#)  
    scleral buckle, encircling, giant retinal tear with slippage on, [2372](#)  
    sclerotomies, vitreous incarceration in, [2373](#)  
    submacular hemorrhage, surgery for, [2370](#)  
    subretinal perfluorocarbon bubble, [2372](#)  
    suprachoroidal hemorrhage (SCH), [2371](#)  
    during vitrectomy, posterior synechiae and small pupil, [2369](#)  
control systems of, [1920](#)  
definition, [1916](#)  
epiretinal membrane management, [1924–1925](#), [1925f](#)

extrusion techniques, [1925–1926](#)  
fatigue failure, [1917](#)  
fluid-air exchange of, [1927](#), [1927f](#)  
fluidics, [1919](#)  
hemostasis, [1930](#)  
infusion system management, [1917–1919](#), [1918f–1919f](#)  
interfacial surface tension management, [1927–1929](#), [1927f](#)  
lens management of, [1923–1924](#), [1924f](#)  
liquid perfluorocarbon, [1928–1929](#), [1929f](#)  
mechanics of, [1917](#)  
microscope requirements of, [1920](#), [1921f](#)

body, [544–545](#), [546f–549f](#)  
    aging of, [555](#), [557f](#)  
chondroitin sulfate in, [544](#)  
collagen in, [544](#), [545f](#)  
contraction of, in proliferative diabetic retinopathy, [1098–1099](#),  
    [1098f](#), [1101f](#)  
degeneration, [277](#), [280f](#)  
fibrillins in, [544](#)  
foreign bodies, intraocular, [281](#), [290f–291f](#)  
hemorrhages, [280](#), [283f–285f](#)  
hyaluronan in, [544](#)  
inflammation, [280–281](#), [289f](#)  
intraocular infections, [280](#), [287f–289f](#)  
liquefaction of, [555](#), [557f](#)  
noncollagenous structural proteins in, [544](#)  
opticin in, [544](#)  
pathology of, [555–572](#)

- persistent hyperplastic primary vitreous, [277–280](#), [282f](#)
- physiology of, [553](#)
- structural changes of, with aging, [555–557](#)
- Terson syndrome, [280](#), [287f](#)

Vitreous abnormalities, of retinitis pigmentosa, [870](#), [870f](#)

Vitreous base, [551](#)

- avulsion, [1762](#), [1762f](#), [2085–2087](#)
- radical excision of, in giant retinal tear surgery, [2076](#)
- shaving, perfluorocarbon liquid (PFCL) and, [1970](#)

Vitreous biopsy, [2298–2300](#), [2668](#), [2669f](#)

- case studies, [2300b–2301b](#), [2301f–2302f](#)
- histologic technique, [2299](#)
- for infections, [2298](#), [2298f](#)
- results, [2299–2300](#), [2300f](#)
- sample of findings in major disease categories, [2298t](#)
- summary of results in intraocular lymphoma, [2299t](#)
- surgical technique, [2298–2299](#), [2298f](#)

Vitreous cells, retinal metastases and, [2462–2468](#)

Vitreous cellular condensations, of primary vitreoretinal lymphoma (PVRL), [2676f](#)

Vitreous cutter, considerations of, [1919](#), [1920f](#)

Vitreous degeneration, [277](#), [280f](#)

Vitreous detachment, in proliferative diabetic retinopathy, [1099f](#)

Vitreous gel

- alterations of, [1063](#)
- traction by, [1072](#)

Vitreous haze, of primary vitreoretinal lymphoma (PVRL), [2676f](#)

## Vitreous hemorrhage

- branch retinal vein occlusion, [1160–1161](#)
- in cavernous hemangioma, [2423](#)
- closed-globe injuries, [2085](#), [2085f](#)
- evidence-based trials and, [2125](#)
- neovascular age-related macular degeneration and, [1358](#), [1359f](#)
- , open-globe injuries, [2096–2100](#), [2098f–2099f](#)
- pediatric vitreoretinal surgery for, [2178](#)
- persistent, [1668–1670](#)
- proliferative diabetic retinopathy and, [2108–2109](#), [2109f](#)

## Vitreous humor, [673](#)

Vitreous incarceration, in sclerotomies, [2373](#)

Vitreous infiltrates, [2662–2664](#), [2664f](#)

Vitreous injections, [836](#)

Vitreous leakage, in transmitted fluorescence, [32–34](#)

Vitreous liquefaction, [555](#), [557f](#)

Vitreous needle tap, for endogenous endophthalmitis, [1705](#)

## Vitreous removal

- retinal adhesion and, [507–508](#)
- vitreoretinal surgery and, [1921–1923](#)

Vitreous traction, and scleral buckles, [1884](#), [1884f](#)

Vitreous “trap” method, [2299](#)

## Vitritis

- in Hodgkin lymphoma, [2670f](#)
- from syphilis, [1645f](#)

Vogt-Koyanagi-Harada (VKH) disease, [1505–1515](#)

- chronic recurrent stage of, [1509–1510](#), [1510f–1511f](#)

clinical description of, [1506–1510](#)  
clinical features of, [1510](#), [1510t](#)  
complications and management of, [1513–1514](#), [1513f–1514f](#)  
differential diagnosis of, [1511–1512](#)  
epidemiology of, [1505–1506](#)  
historical aspects of, [1505](#), [1506b](#)  
imaging studies of, [1511](#), [1512f–1513f](#)  
investigations in, [1511](#)  
lumbar puncture for, [1511](#)  
pathology and pathogenesis of, [1510–1511](#), [1510f–1511f](#)  
prodromal stage of, [1506](#)  
prognosis of, [1514](#)  
treatment of, [1512–1513](#), [1513b](#)  
uveitic stage of  
    acute, [1506–1507](#), [1507f–1510f](#)  
    chronic, [1507–1509](#), [1509f–1510f](#)

Vogt-Koyanagi-Harada (VKH) syndrome, [1779](#)  
    nonrhegmatogenous retinal detachment in, [1835–1836](#), [1836f](#)

Voltage-dependent anion channel (VDAC), [722](#)

Vomiting, in fluorescein injection, [3](#)

von Graefe, Albrecht, [1465](#)

Von Hippel-Lindau syndrome, wide-field imaging for, [160f](#)

von Hippel-Lindau (VHL) disease, [2423](#), [2427](#)  
    antiangiogenic pharmacotherapy for, [2435](#)  
    diagnosis of, [2432](#)  
    gene and protein in, [2427–2428](#)  
    history of, [2427](#)

ocular

clinical features of, [2428–2431](#), [2428f–2431f](#)

treatment of, [2432–2435](#)

screening in, recommended intervals for, [2432t](#)

surveillance of, [2432](#)

von Leber, Theodor, [1188](#)

Voriconazole

for endogenous endophthalmitis, [1704](#), [1704b](#)

intravitreal, [1704–1705](#)

Vortex vein

ampulla, varix of, [53f](#), [66](#)

compression, uveal effusion and, [1485](#)

decompression, for uveal effusion syndrome, [1490](#)

Vortex veins, [1890](#)

*Vsx2/Chx10* gene, [376t](#), [378](#)

## W

Wagner syndrome, [937t](#)

differential diagnosis of, [943](#)

ocular features of, [939–940](#), [940f](#)

overview of, [939](#)

Waldenström macroglobulinemia, [2671](#)

“Wash out” phenomenon, [2642](#)

Watershed zone, [48](#)

Wavelength discrimination, [330](#)

Wegener's Granulomatosis, [Granulomatosis with polyangiitis](#)

Weiss ring, [553](#), [556f](#)

Weissenbacher-Zweymuller syndrome  
    extraocular features of, [942](#)  
    general features of, [942](#)

Welder's maculopathy, [1749–1750](#), [1749f–1750f](#)

Western blot (WB), [1564–1567](#)

White dot syndromes, [66](#), [70f](#), [1567–1568](#)

White ischemic thickening, in blocked retinal fluorescence, [14](#)

White spot syndromes, [1516–1561](#)

White-centered retinal hemorrhages, [2664](#), [2664f](#)

Whitening, retinal, central retinal artery occlusion and, [1137](#), [1137f](#)

Whole-exome sequencing, [720](#)

Wide-angle angiography, benefit of, [2](#)

Wide-angle fundus, [2584f](#)

Wide-angle photography, [2571](#)  
    retinal, in retinoblastoma, [2391](#)

Wide-field angiography, of branch retinal vein occlusion, [1158](#),  
[1158f](#)

Wide-field illumination, [2035–2036](#)

Wide-field imaging, [123](#), [143–166](#)  
    capabilities and optical principles in, [146–147](#)  
    clinical utility of, [147–161](#)  
        age-related macular degeneration, [161](#), [161f–162f](#)  
        central serous chorioretinopathy, [161](#), [161f](#)  
        diabetic retinopathy, [147–148](#), [148f](#)  
        myopia, [155–157](#)  
        ophthalmic oncology, [159–160](#), [159f–160f](#)  
        other retinal vascular conditions, [148](#), [150f](#)

- pediatric retina, [155](#), [155f](#)
- retina detachment, [155–157](#), [156f–157f](#)
- retinal and choroidal dystrophies, [157–159](#), [157f–158f](#)
- retinal venous occlusions, [148](#), [149f–150f](#)
- uveitis, [148–155](#), [151f–154f](#)
- future directions of, [162–163](#), [163f](#)
- historical perspective in, [143](#)
- historical systems in, [143–144](#)
- limitations of, [162](#), [162f](#)
- modern systems in, [144–146](#)
- terms in, [143](#)

Wound-healing process, [1859–1860](#)

Wounds, retinal incarceration in, retinectomy for, [2059–2061](#)

Wyburn-Mason syndrome, [2423](#), [2453–2454](#), [2453f](#), [Racemose hemangiomatosis](#)

Wyburn-Mason type, arteriovenous malformation, [30f](#)

## X

X-82, for age-related macular degeneration, [1407](#)

Xanthophyll, [9](#), [15](#), [1185–1186](#)

X-chromosome opsin genes, [332](#)

X-linked color vision defects, [331](#)

X-linked complete CSNB, [260](#), [260f](#)

X-linked cone dysfunction syndrome with dichromacy, [1010](#)

X-linked incomplete CSNB, [260](#), [260f](#)

X-linked juvenile retinoschisis (XLRs)

- full-field ERG and, [254–255](#), [260f](#)
- second-order neuron dysfunction and, [261](#)

gene augmentation therapy for, 754

X-linked recessive inheritance, 712–713, 712*f*

X-linked retinitis pigmentosa (XLRP), 865, 868*f*, 1001–1002, 1002*f*  
genes, 900–901

X-linked retinoschisis, 937*t*, 943–946

- clinical features of, 943–944
- congenital, pediatric vitreoretinal surgery for, 2185–2186, 2185*t*
- differential diagnosis of, 944–945, 945*f*
- electrophysiology of, 944, 945*f*
- gene therapy for, 946
- genetic counseling for, 945
- laser for, 945
- management of, 945
- ocular features of, 943–944, 944*f*
- optical coherence tomography of, 944, 944*f*
- overview of, 943
- pharmacologic treatment of, 945
- retina and/or progenitor cell transplantation for, 946
- retinal nuclear receptor (NR2E3)-related diseases and, 947
- surgery for, 945
- treatment of, 945–946
- visual psychophysics of, 944

XLRS, X-linked juvenile retinoschisis (XLRS)

## Y

Y402H variant, AMD and, 631–632

Young patient, branch retinal vein occlusion in, 1158–1159

## Z

Zeaxanthin, [582–583](#), [1408](#)

*Zfx1b* gene, [376t](#)

Zimmerman, Lorenz, [2502](#)

Zimura, for age-related macular degeneration, [1407–1408](#)

Zinc supplement, for AMD, [1276](#)

Zone I retinopathy of prematurity, [1253](#)

Zonular traction tuft, [560f](#)

Video Table of Contents	80
Contributors	87
Video Contributors	149
Dedication	155
Preface	159
Volume One	161
Part 1 Retinal Imaging and Diagnostics	162
1 Fluorescein Angiography	163
Basic Principles	165
Equipment (Box 1.1)	168
Technique	173
Developing a Photographic Plan	184
Interpretation	186
Abnormal Fluorescein Angiogram	198
Acknowledgments	257
References	257
2 Clinical Applications of Diagnostic Indocyanine Green Angiography	259
Introduction	260
History	261
Chemical and Pharmacokinetics	262
Toxicity	263
Instrument Comparison	264
Injection Technique	267
Indocyanine Green Angiography Interpretation	268
References	307

3	Optical Coherence Tomography	319
	Physical Principles of Optical Coherence Tomography	320
	Quantitative Analysis of OCT Datasets	326
	Normal Macular Anatomy	330
	SD-OCT in Retinal Disorders	334
	OCT Angiography	378
	Future Directions	401
	Disclosures	403
	Acknowledgments	403
	References	403
4	Autofluorescence Imaging	430
	Basic Principles	431
	Techniques of Fundus Autofluorescence Imaging	435
	Interpretation of Fundus Autofluorescence Images	442
	Clinical Applications	446
	Functional Correlates of Fundus Autofluorescence Abnormalities	476
	References	477
5	Wide-Field Imaging	487
	Introduction	488
	Historical Perspective and Terms	488
	Historical Wide-Field Imaging Systems	489
	Modern Wide-Field Imaging Systems	491
	Overview of Imaging Capabilities and Optical Principles	496
	Clinical Utility of Wide-Field Imaging	497
	Limitations	531
	Future Directions	532
	Conclusion	534

8 Image Processing	628
Introduction	628
History of Retinal Imaging	629
History of Retinal Image Processing	631
Current Status of Retinal Imaging	632
Fundus Imaging	632
Optical Coherence Tomography Imaging	634
Areas of Active Research in Retinal Imaging	639
Clinical Applications of Retinal Imaging	642
Image Analysis Concepts for Clinicians	644
Fundus Image Analysis	661
Optical Coherence Tomography Image Analysis	679
Multimodality Retinal Imaging	689
Future of Retinal Imaging and Image Analysis	693
References	694
9 Electrogenesis of the Electroretinogram	712
Introduction	712

Generation of Extracellular Potentials: General Concepts	716
Approaches for Determining the Origins of the Electroretinogram	721
Standard ERG Tests in the Clinic	724
Origin of the a-Wave	735
Origin of the b-Wave	747
Origin of the d-Wave	755
Origin of the Photopic Fast-Flicker ERG	756
Origin of the Multifocal ERG	757
ERG Waves From Proximal Retina	760
Closing Remarks	776
References	777
10 Clinical Electrophysiology	789
Standard Full-Field ERG	790
Focal ERG	824
Other Special Responses or Techniques in ERG	834
Electro-Oculogram	840
Visual Evoked Potential	842
Simultaneous Recording of Focal Macular ERG and VEP	843
References	845
11 Diagnostic Ophthalmic Ultrasound	852
Introduction	854
Ultrasound – Past and Present	854
Examination Techniques	855
Ultrasound in Intraocular Pathology	863
Ultrasound Imaging Used to Differentiate Ocular Disease	939
Future Developments	944
Acknowledgments	945
References	945
12 Color Vision and Night Vision	951
Overview	951
Rod and Cone Functions	952
Visual Pathways for Rod and Cone Functions	957

From Day Vision to Night Vision	959
Color Vision	962
Variations in Human Color Vision	969
Clinical Evaluation of Color Vision	973
New Developments in Color Vision Research	986
Adaptive Optics (AO) Retinal Imaging System	987
References	989
13 Visual Acuity and Contrast Sensitivity	994
Visual Acuity Tests	995
Contrast Sensitivity Tests	1004
References	1012
14 Visual Fields in Retinal Disease	1017
Introduction	1018
Principles of Perimetry	1021
Methods of Visual Field Testing	1022
Perimetry in Specific Retinal Diseases	1032
Future of Perimetry in Retinal Disease	1068
Conclusions	1071
References	1071
Part 2 Basic Science and Translation to Therapy	1092
Section 1 Anatomy and Physiology	1093
15 The Development of the Retina	1094
Introduction	1094
Embryology of the Eye	1095
The Eye Field	1097
Patterning the Retinal, RPE, and Anterior Domains of the Optic Cup	1101
Histogenesis of the Retinal Cell Types	1104
Inner Retinal Development	1109
Photoreceptor Development	1116
Ganglion Cell Death	1119
Retinal Maturation	1121
Conclusion	1122

References	1123
16 Structure and Function of Rod and Cone Photoreceptors	1132
Introduction	1134
Photoreceptor Fundamentals	1135
Photoreceptor Outer-Segment Structure	1140
Phototransduction	1148
Inner Segment and Connecting Cilia	1163
Photoreceptor Synaptic Terminal	1168
Photoreceptor Dysfunction and Disease	1171
References	1177
17 Function and Anatomy of the Mammalian Retina	1201
Visual Illusions and Multiple Channels	1202
Neuronal Communication: Chemical and Electrical	1204
Gross Retinal Morphology	1208
Classification of Retinal Cells	1214
Gene Therapy to Cure Color Blindness	1284
New Tools to Identify Ganglion Cell Types	1285
Clinical Relevance of Functional Anatomy	1287
Conclusions	1292
Acknowledgments	1293
References	1294
18 Cell Biology of the Retinal Pigment Epithelium	1325
Embryology	1326
Anatomy and Histology	1327
Specialized Functions of the RPE	1340
References	1353
19 Cell Biology of Retinal Glia	1373
Introduction	1374
Retinal Microglia	1377
Retinal Astrocytes	1384
Müller Glial Cells	1387
References	1421
20 Retinal and Choroidal Vasculature	1435

History of Retinal Ischemia	1440
Normoxia	1440
Hyperoxia	1441
Hypoxia	1442
Adult Retinal Hypoxia and Etiology	1456
Adult Choroidal Ischemia	1463
Conclusions	1466
References	1466
21 Mechanisms of Normal Retinal Adhesion	1486
Models for Measuring Retinal Adhesion	1488
Adhesive Force and Environmental Factors	1489
Mechanical Forces Inside the Subretinal Space	1498
Pharmacologic Modification of Adhesion	1515
Implications for Vitreoretinal Surgery	1519
Pathophysiology of Serous Detachment	1522
Conclusions and General Implications	1527
References	1529
22 Structure, Function, and Pathology of Bruch's Membrane	1541
Introduction, History, Embryology	1542
Structure of Bruch's Membrane in the Young Adult Eye	1545
Bruch's Membrane in an Aged Eye	1549
Function of Bruch's Membrane	1556
Pathology of Bruch's Membrane	1569
Conclusion	1581
References	1582
23 Vitreous and Vitreoretinal Interface*	1613
Biochemistry	1613
Anatomy and Histology	1616
Physiology	1640
Pathology	1641
References	1687
Section 2 Basic Mechanisms of Injury in the Retina	1708

Section 2 Basic Mechanisms of Injury in the Retina	1708
24 Mechanisms of Oxidative Stress in Retinal Injury	1709
Overview of Oxidative Stress in the Retina	1710
Retinal Diseases Related to Oxidative Stress	1712
Oxidative Injury to the Retina	1719
Retinal Therapies Targeting Oxidative Stress	1731
Conclusions	1737
References	1737
25 Mechanisms of Endoplasmic Reticulum Stress in Retinal Disease	1757
Introduction	1758
The Endoplasmic Reticulum	1758
ER Stress and Unfolded Protein Response Signaling	1761
Retinal Diseases Associated With ER Stress	1767
Summary	1780
References	1780
26 Cell Death, Apoptosis, and Autophagy in Retinal Injury	1789
Introduction	1790
Modes of Cell Death	1791
Autophagy and Cell Maintenance	1796
Age-Related Retinal Cell Loss	1802
Retinal Damage: Death and Repair	1804
Therapeutic Options	1817
Conclusions	1826
References	1827
27 Inflammation and Immune Responses in Retinal Health and Disease	1855
Introduction	1857
Innate Defenses in the Maintenance of Retinal Health	1859
Autoinflammation and Autoimmunity	1866
Inflammation, Vascular Regulation, and Pathologic Angiogenesis (Neovascularization)	1871
Inflammation and AGE-Related Macular	

Degeneration	
Targeting Inflammation Through Molecular Stratification: Genetics and Beyond	1881
Conclusion	1882
References	1883
28 Basic Mechanisms of Pathologic Retinal and Choroidal Angiogenesis	1896
Introduction	1897
Mechanisms of Choroidal Angiogenesis	1911
Angiogenic and Antiangiogenic Factors in Neovascularization	1918
Conclusions	1926
References	1926
29 Blood–Retinal Barrier, Immune Privilege, and Autoimmunity	1956
Introduction	1957
Blood–Ocular Barrier	1959
Basic Concepts of Immunology	1960
The Eye as an Immune-Privileged Site	1966
Retinal Autoimmunity	1975
Conclusion	1980
References	1981
30 Mechanisms of Macular Edema and Therapeutic Approaches	1993
Introduction	1994
Macular Edema as a Result of Various Disease Mechanisms	1995
Clinical Endpoints in Macular Edema	2018
Treatment of Macular Edema	2020
Discussion and Conclusion	2046
References	2047
31 Cellular Effects of Detachment and Reattachment on the Neural Retina and the Retinal Pigment Epithelium	2067
Introduction	2068
Use and Limitations of Animal Models in the Study	2068

of Retinal Detachment	2068
Cellular Changes in Response to Retinal Detachment	2070
Chronic Retinal Detachment and Proliferative Vitreoretinopathy	2088
Retinal Reattachment	2093
References	2098
32 Serous and Hemorrhagic Detachment of the Sensory Retina and Pigment Epithelium	2105
Introduction	2106
Anatomic Constituents	2107
Mechanism of Normal Attachment	2108
Mechanisms of Impairment	2112
Clinical Manifestations of PED and Serous Retinal Detachments	2115
Conclusion	2122
References	2122
Section 3 Genetics	2131
33 Genetic Mechanisms of Retinal Disease	2132
Introduction	2133
Basic Concepts in Human Genetics	2134
The Human Genome	2148
Genetic Testing Methods	2155
Future Prospects	2159
References	2160
34 Mitochondrial Genetics of Retinal Disease	2166
Mitochondrial Origins	2167
Mitochondrial Structure	2167
Mitochondrial DNA (mtDNA)	2169
Mitochondrial Function	2172
Electron Leakage and ROS Formation	2172
Localization of Mitochondria Within the Retina and Optic Nerve	2173
Influences of mtDNA on Cell Function	2174

35 Epigenetic Mechanisms of Retinal Disease	2199
Introduction	2200
Major Factors of Epigenetic Regulation	2201
Epigenetic Factors in the Retina	2205
Epigenetic Mechanisms in Retinal Development	2207
Epigenetic Mechanisms in Retinal Diseases	2212
Perspectives and Challenges of Epigenetics	2225
References	2228
Section 4 Translational Basic Science	2235
36 Gene Therapy for Retinal Disease	2236
Background: Preclinical Gene Therapy Studies	2238
History of Retinal Gene Therapy	2253
Current Status of Retinal Gene Therapy Trials: Retinal Diseases Evaluated in Human Clinical Trials	2260
Promises and Challenges of Bringing Retinal Gene Transfer From Bench to Bedside	2266
Conclusion	2274
References	2275
37 Stem Cells and Cellular Therapy	2292
Stem Cells as Therapeutics to Treat Retinal Disease	2293
Definitions	2294
Retinal Stem and Müller Glial Cells	2299
RPE Cells	2305
Adult Bone Marrow-Derived Endothelial Progenitor Cells	2318
Human Clinical Trials Using Stem Cells for the Treatment of Retinal Diseases	2325
Discerning the Legitimacy of A Human Stem Cell Treatment	2327
Concluding Remarks	2329
Acknowledgments	2330
References	2330
38 Nanomedicine in Ophthalmology	2345
Introduction	2347
General Principles of Nanotechnology and	

Introduction	2347
General Principles of Nanotechnology and Nanomedicine	2347
Properties of Nanomachines	2351
Applications to Ophthalmology	2357
Obstacles to Incorporation of Nanotechnology Into Ophthalmology	2405
Conclusion	2407
References	2409
39 Neuroprotection	2439
History and Definitions	2440
Neuroprotection Through the Serotonin Pathway	2445
Neurotrophic Factors for Retinitis Pigmentosa	2446
CNTF Protein and Historical Selection	2447
CNTF Phase I Trial for Human Photoreceptor Degeneration	2450
New Technology for Endpoints for Photoreceptor Degenerations	2455
Delivery of Neurotrophins	2455
References	2485
40 Drug Delivery	2506
Introduction	2507
A Brief History of the Field of Drug Delivery	2507
Drug Delivery	2509
Gene Delivery	2516
Cellular Delivery for Sustained Drug Delivery	2520
Routes of Delivery to the Retina	2522
Pharmacokinetics in the Eye	2535
References	2537
41 Retinal Laser Therapy	2550
Introduction	2551
Basics of Lasers	2554
Interactions of Light With Tissue	2561
Monitoring Retinal Temperature	2587

Volume Two Medical Retina	2596
Section 1 Retinal Degenerations and Dystrophies	2597
42 Retinitis Pigmentosa and Allied Disorders	2598
Introduction	2598
Early History	2599
Typical Retinitis Pigmentosa	2600
Complicated Retinitis Pigmentosa	2656
Differential Diagnosis – Phenocopies of Retinitis Pigmentosa	2659
Differential Diagnosis: Pseudoretinitis Pigmentosa	2674
Basic Science	2683
Genetic Consultation	2713
Support Services	2717
Treatment	2719
Future Management	2732
Acknowledgment	2740
References	2741
43 Hereditary Vitreoretinal Degenerations	2820
Snowflake Vitreoretinal Degeneration	2823
The Chromosome 5q Retinopathies	2829
Chondrodysplasias Associated With Vitreoretinal Degeneration	2835
X-Linked Retinoschisis	2841
Retinal Nuclear Receptor (NR2E3)-Related Diseases	2851
Other Vitreoretinal Degenerations and Vitreoretinopathies	2855
References	2857
44 Macular Dystrophies	2875
Introduction	2875
The Initial Approach to a Patient With Macular Dystrophy	2878
Best Macular Dystrophy	2883
Stargardt Disease	2905
Stargardt-Like Dominant Macular Dystrophy (SLDMD)	2931
PROM1-Associated Macular Dystrophy	2936

Pattern Dystrophy	2937
Sorsby Fundus Dystrophy	2948
Autosomal Dominant Radial Drusen (Doyme Honeycomb Retinal Dystrophy, Malattia Leventinese)	2952
North Carolina Macular Dystrophy	2959
Spotted Cystic Dystrophy	2961
Dominant Cystoid Macular Dystrophy	2962
Fenestrated Sheen Macular Dystrophy (FSMD)	2963
Glomerulonephritis Type II and Drusen	2964
Maternally Inherited Diabetes and Deafness	2965
Acknowledgments	2966
References	2967
45 Hereditary Choroidal Diseases	2997
Introduction	2998
Choroidal Atrophy Phenotypes	3000
Gyrate Atrophy of the Choroid and Retina	3004
Choroideremia	3007
Clinical Phenotypes Resembling Hereditary Choroidal Diseases	3013
Conclusion	3019
References	3020
46 Abnormalities of Rod and Cone Function	3028
Introduction	3029
Disorders of the Cone System	3029
Congenital Stationary Night Blindness	3040
Progressive Cone Dystrophies	3049
Conclusions	3052
References	3052
Section 2 Retinal Vascular Disease	3065
47 The Epidemiology of Diabetic Retinopathy	3067
Introduction	3068
Incidence and Progression of Diabetic Retinopathy and Incidence of Clinically Significant Macular Edema	3072
The Relationship of Race/Ethnicity to Diabetic Retinopathy	3075

Genetic Factors	3077
Sex	3078
Age and Puberty	3078
Type 2 Diabetes in Children and Adolescents	3080
Duration of Diabetes	3080
Age at Diagnosis	3083
Glycemia	3083
C-Peptide Status	3091
Exogenous Insulin	3091
Blood Pressure	3092
Proteinuria and Diabetic Nephropathy	3096
Serum Lipids and Lipid Lowering	3097
Smoking	3099
Alcohol	3099
Body Mass Index (BMI)	3100
Physical Activity	3101
Socioeconomic Status	3101
Hormone and Reproductive Exposures in Women	3102
Comorbidity and Mortality	3104
New Medical Interventions	3105
Public Health Applications of Epidemiologic Data	3106
Conclusion	3108
References	3109
48 Diabetic Retinopathy	3132
Introduction	3133
Anatomic Lesions	3133
Biochemical Mechanisms in the Pathogenesis of Diabetic Retinopathy	3139
Genetic Factors in the Pathogenesis of Diabetic Retinopathy	3149
Other Ocular Factors	3154
Retinopathy in Different Forms of Diabetes	3156
Animal Models in the Study of Diabetic Retinopathy	3159
Cell Culture Studies	3163

Cell Culture Studies	3163
Conclusion	3166
Acknowledgments	3166
References	3166
49 Diabetes Mellitus	3191
Introduction	3192
Prevalence of Retinopathy	3193
Glycemic Control and Retinopathy	3193
Goals of Treatment	3194
Glycemic Control: Pharmacologic Treatment	3195
Initiation and Titration of Therapy	3203
References	3206
50 Nonproliferative Diabetic Retinopathy and Diabetic Macular Edema	3210
Natural Course of Nonproliferative Diabetic Retinopathy	3211
Clinical Evaluation of Nonproliferative Diabetic Retinopathy	3217
Clinical Evaluation of Diabetic Macular Edema	3239
Management of Nonproliferative Diabetic Retinopathy and Diabetic Macular Edema	3251
Conclusion	3282
References	3283
51 Proliferative Diabetic Retinopathy	3305
Pathogenesis of Proliferative Diabetic Retinopathy	3307
Origin and Early Recognition of Preretinal New Vessels	3309
Natural Course of Proliferative Diabetic Retinopathy	3315
Relationship of Proliferative Diabetic Retinopathy to Type and Duration of Diabetes	3333
Proliferative Diabetic Retinopathy and Blood Glucose Control	3336
Early Worsening of Retinopathy With Improved Glycemic Control	3337
Absence of Proliferative Diabetic Retinopathy in Individuals With Diabetes of Extreme Duration	3338

Peripheral Diabetic Retinal Lesions and the Risk of Retinopathy Progression	3341
Other Risk Factors for Proliferative Diabetic Retinopathy	3341
Management of Proliferative Diabetic Retinopathy	3343
Current Techniques of Panretinal Photocoagulation	3365
Regression of New Vessels After Initial Photocoagulation and Indications for Retreatment	3370
Complications of PRP	3373
Antiangiogenic Therapies for Proliferative Diabetic Retinopathy	3376
Indications for Vitrectomy	3378
Telemedicine Approaches for the Detection of Proliferative Diabetic Retinopathy	3380
Conclusion	3380
References	3382
